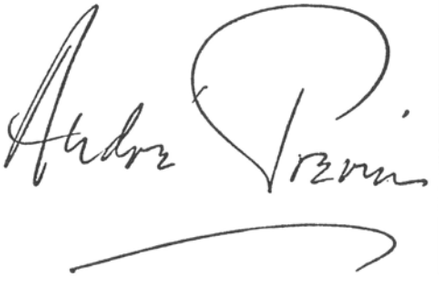
# Foreword

I admire David Munrow enormously, for a variety of reasons. He is, without question, a formidable virtuoso; to hear him play any of the dozens of instruments which have almost become his private domain, is to listen to a consummate artist. He is also the undisputed expert in the field of medieval and renaissance music, and his Early Music Consort of London is a shining light in the vast field of British music and musicians. He is possessed of an acerbic wit, is a popular broadcaster, tells a great anecdote, has with it all the face of a slightly immoral schoolboy, and finally, is shorter than I am, a statistic I cherish.

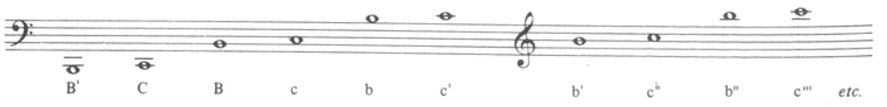
In this book, you and I will at last be able to find out all about the music and the instruments which David and his musicians have done so much to revive. My personal work involves me with all the instruments of the modern symphony orchestra. In my ignorance, I always thought of that field as a fairly all-encompassing one. Therefore, it is amazing and entertaining and valuable to find out, through this volume, that the ancestry of all these modern instruments is a lifetime's study. I don't mean to imply that this book is just a scholarly research trip into the past. What makes it so readable is the way it brings to life conditions under which the musicians of bygone days had to work, just what the day-to-day routine of a minstrel or town bandsman or member of the royal household was like. And it is made abundantly clear that being a professional shawm- or rommelpot-player was not always a bed of roses.

No one is better qualified to write on this subject than David Munrow. His practical experience and theoretical knowledge have produced a book which will appeal to the specialist and general reader alike. His ability to mix scholarly detail with amusing stories should make this volume find a place on thousands of bookshelves.



## A note on pitch

It should be remembered that, during the Middle Ages and Renaissance, pitch was far from standardized. In this book, where specific pitches are referred to, the following system of pitch notation has been used:



In giving the ranges of wind instruments the following conventions have been observed: the basic compass is given in white notes, with a line indicating the fully chromatic range. Black notes are used for extensions to the basic compass (*eg* low pedal notes on the sackbut, high overblown notes on the cornett or flute), described by Praetorius as 'falsetto' notes, obtainable only by skilled players.

With wind instruments there is also a problem of terminology in order to distinguish clearly the different sizes of the same family. Renaissance musicians were far from consistent in this matter and even today there is still a certain amount of confusion. Some makers refer to the bass recorder (lowest note f) or the bass rackett (lowest note F) as *bassett* instruments, and there are further complications through the common English habit of designating the soprano recorder (lowest note c'' or d'') *descant* and the alto (lowest note f' or g') *treble*. In this book the following names have been used: great bass, quint bass or quart bass, bass, tenor, alto, soprano, sopranino.

## The performers

The following performers appear in photographs in this book: unless otherwise stated in the captions, the instruments shown are from their own collections.

p9 David Munrow (oriental shawm)

# Preface

In ten years of giving concerts of early music there is one question which I have been asked with predictable regularity: please will you explain the instruments? This book is a response to the hundreds of people who have asked me that question and to my own gradual awareness that I was certain of very few of the answers. For me, writing the book has been the same sort of process of discovery that I hope it will be for those who read it. For the general reader I have tried to provide a balanced introduction to early instruments by summarizing, and in some cases no doubt over-simplifying, the vast amount of research which has been done in recent years. For the specialist who wishes to follow up certain instruments in greater detail the extensive footnotes should provide fruitful sources of further reading. Wherever possible references have been given to the works which have been consulted, including books and periodicals (in English only) as well as modern editions and facsimiles. I have endeavoured to give as much information as possible about the social and historical background, since without it an understanding of the function of early instruments must remain incomplete. The division of the book into two parts (before and after *c.*1400) is intended to show which instruments properly belong to the Middle Ages and which to the Renaissance, a fundamental point that, through the enthusiasm of early music performers (including myself), has sometimes been overlooked. Chapter 5 deals with both medieval and renaissance percussion instruments and acts as a bridge between the two parts. It should be noted that Part Two describes the instruments which *developed* after 1400, and where a medieval instrument continued in use more or less unaltered during renaissance times, it is fully dealt with in Part One. Thus, details of the following are to be found in Part One only: pipe and tabor, gemshorn, portative organ, clavichord, psaltery, dulcimer, and tromba marina.

In order not to cram the book with information which would be superfluous for many readers, I have assumed a working knowledge of modern orchestral instruments and some acquaintance with the history of music before 1600. Readers who do require guidance on the latter point are referred to Gustave Reese's two books, *Music in the Middle Ages* (Norton, New York 1940), and *Music in the Renaissance* (Norton, New York 1954), or to the earlier chapters by Alec Harman in *Man and his Music* (Barrie and Rockliff, London 1962). Inevitably, since new discoveries are still being made and new evidence is still coming to light, this book will be out of date in some respects before it is published. Even as I write, the appearance of Sybil Marcuse's *A Survey of Musical Instruments* (David and Charles, London 1975) makes available much fascinating new information too late to be included here. Readers who are eager to keep abreast of all the latest developments are strongly advised to subscribe to the periodicals regularly mentioned in the footnotes. They will find especially valuable the journal *Early Music* (published quarterly by the Oxford University Press) which contains the most up-to-date information available about makers of early instruments and details of where replicas may be obtained.

Any fresh attempt to contribute to the study of musical instruments must inevitably draw on the work of other writers in this field. My debts are too numerous to acknowledge in detail here: a full account of the sources of information I have used is given in the footnotes, whilst the authors to whom I am most indebted are mentioned in the text itself. Special tribute must be paid to the work of the Galpin Society: through its annual journal and the individual publications of its members a vast amount of important research has appeared in print. I would particularly like to acknowledge the influence of the writings of Anthony Baines. It was the publication of his *Woodwind Instruments and their History* (Faber, London 1957) which first stimulated my interest in early instruments; in writing this book I have found myself constantly referring to his *European and American Musical Instruments* (Batsford, London 1966) for information about instrument construction and the clarification of distinctions between different instrumental types. His lucid, concise, and informative style has been my model.

In writing this book I have benefited from the practical help and co-operation of a number of people. To James Blades, John Caldwell, Christopher Hogwood, Edgar Hunt, Christopher Monk, Mary Remnant, and James Tyler my thanks are due for reading various chapters and giving me their advice and comments. Between them they spotted an alarming number of errors and inconsistencies, though for any that may remain I of course take full responsibility. I am also grateful for the assistance I have received from Clifford Bartlett, Donald Gill, Ian Harwood, Robert Spencer, and John Thomson. To the Librarian of the University of Leicester my thanks are due for allowing me to borrow, for an extended period, a large number of books greatly exceeding my allotted quota. Over the years I have learnt a great deal from my friends and colleagues in the Early Music Consort of London, many of whom appear in the illustrations of this book. It is from their study and skills that much of my practical knowledge has been derived. To James Tyler I owe a special debt of gratitude. In endless conversations over the last few years he has constantly stimulated my imagination and regularly challenged pre-conceived ideas and woolly thinking. He has also placed all the fruits of his own research at my disposal, and, with equal generosity, allowed me to borrow freely from his extensive collection of books and articles. Many museums, libraries, and publishers have kindly given permission to reproduce illustrations; full acknowledgements will be found in the captions.

To the Oxford University Press my thanks are due for the patience and courtesy by which I was allowed to over-run a whole series of deadlines. Without the help and encouragement of Anthony Mulgan and Sally Wright I doubt if this book would ever have been completed. I am most grateful to Sally Wright for all the assistance she has given me, particularly with the time-consuming task of organizing the illustrations. Without the support of my wife, Gill, however, this book would never have been started, let alone finished. Gill has managed to discreetly remind me of my promise to write it at the moments when I was most inclined to forget, encouraged me to carry on at the moments when I was most liable to give up, and always been ready to discuss things when I got stuck or sit down at any hour of the day or night and type out a new section as soon as it was written. I think she is now the only person left who can actually read my handwriting. From the first draft to the final proof-reading her help has been invaluable.

# Introduction

The story of musical instruments is almost as old as that of mankind: the beginnings lie shrouded in pre-history and the process of evolution has been a gradual one, amazingly slow in the early stages. Music itself was a slow developer amongst the other arts: the introduction to Europe of many medieval instruments coincided with the first attempts at writing measured part-music, a fundamental process of composition which might be compared to learning to paint in colour, to write in verse, or to construct a stone archway. Yet when Léonin and Pérotin produced the earliest monuments of polyphony it was in the shadow of the great cathedral of Notre Dame (started in the year 1163) when Europe had finally emerged from the Dark Ages and men were looking back for inspiration to the art, architecture, and literature of the Greek and Roman civilizations. The so-called 'Renaissance of the twelfth century' which witnessed such important musical developments also saw the establishment of universities at Paris, Montpellier, Oxford, Bologna, and Salerno, a new learning and literature in Latin, and the flowering of troubadour poetry and the drama of the medieval church. Amongst these other arts music was something of a beginner, and the instruments of music were still at an early stage in their development. However, classical ideas and ideals, as interpreted by the medieval theorists, were to exercise a profound effect on their use, representation, and subsequent evolution.

Evolution is perhaps a dangerous word to use, since it is a mistake to view the history of musical instruments in terms of the survival of the fittest. The extinction of a particular species has generally been the result of changing taste or fashion rather than inherent weakness; the musicians of the Middle Ages and Renaissance overcame any shortcomings or limitations which might seem apparent from a twentieth-century viewpoint. Their instruments perfectly fulfilled the musical requirements of the society to which they belonged and few of them can be dismissed as primitive or regarded merely as prototypes. The majority of them played a vital role in musical life, their natural habitat was the highly civilized *milieu* of the European courts, and their repertoire included some of the most sophisticated art-music of the times. Nor should the skill and artistry of the performers be underestimated; whilst we shall never know precisely how Dufay sang or Dowland played we may be sure that in both technique and interpretation they were amongst the supreme masters of any age. The professional musicians then combined versatility with virtuosity just as modern folk musicians still do now in countries such as Greece, Turkey, the Balkans, and the Middle East.

Compared to the instruments of the modern symphony orchestra (the product of man's *conscious* selection) those in use before 1600 are clearly limited in many respects. The wind instruments especially demonstrate severe restrictions of compass, tonal range, and volume which, although compatible with their original function, prevented their continued use in later ages. Yet to some extent all modern orchestral instruments represent a compromise in terms of sound in order to facilitate greater technical control and dexterity. Whilst the brass and woodwind departments provide a vivid example of man's scientific ingenuity, there is a debit side to all the mechanical improvements and innovations of the nineteenth century. There is no orchestral instrument as strident as the shawm, as sweet as the gemshorn, or as hollow as the panpipes, nothing to compare with the nasal edginess of the rebec or the biting rattle of the tromba marina, nothing to match the vocal timbre of the cornett or the rich buzz of the crumhorn and regal. And with plucked instruments the renewal of interest in music before 1600 has brought back into being a bewildering panoply of subtle and exotic sounds previously lost to European musical life outside folk music. The people of the Middle Ages and Renaissance liked gorgeous colours in their clothes, sharp contrasts in their paintings, and highly spiced dishes at their table. The characteristics of their musical instruments were equally individual and uncompromising.

The revival of interest in early instruments began during the last century with the work of (amongst others) François Joseph Fétis (1784–1871) whose collection of seventy-eight instruments provided the nucleus for that of the Brussels Conservatoire (now known as the Brussels Museum of Musical Instruments). Through the enthusiastic direction of Victor Mahillon (1841–1924) the collection swelled to over 1,500 items including a number of renaissance replicas which Mahillon commissioned. The best-known pioneers were both English and, curiously enough, born in the same year: Arnold Dolmetsch (1858–1940)[1] and Francis W. Galpin (1858–1945).[2] Since their day detailed research has multiplied, amassing an enormous body of material about the history, construction, and use of early instruments. The nature of the evidence is so varied that it may be helpful to summarize the main sources of information, bearing in mind that evidence is often conflicting or misleading and not always to be accepted at face value.

### 1. ORIGINAL INSTRUMENTS

Instruments from before *c.*1600 which have been preserved in good (and unaltered) condition are relatively rare. Many museums confidently exhibit instruments which have been drastically 'improved' in later centuries and surviving instruments usually require restoration or at least the replacement of strings, reeds, crooks, keys, or mouthpieces. Whilst stringed instruments, like good wine, mature with age, wind instruments can eventually fall into a decline since wooden bores warp easily and metal tends to become brittle with age. Informed opinion now favours the principle of preserving intact what original instruments remain, avoiding any radical form of renovation. Otherwise future generations will be left without any true originals to study or copy.

Medieval survivals in any state of preservation are naturally scarce and dispersed in collections all over the world. For a survey of them readers are referred to Frederick Crane's *Extant Medieval Musical Instruments* (University of Iowa Press, Iowa City 1972). With renaissance instruments, many more examples still exist and three European collections are especially valuable – those of the Brussels Museum of Musical Instruments, the Staatliches Institut für Musikforschung, West Berlin, and the Kunsthistorisches Museum, Vienna. Some of the finest specimens from these, and other important collections, are included in Anthony Baines' *European and American Musical Instruments* (Batsford, London 1966).

### 2. FOLK INSTRUMENTS

The dearth of original medieval instruments is more than compensated for by the existence of countless folk-music survivals. In many countries folk music has preserved medieval traditions of making and playing and quite a number of instrumental types have lived on, virtually unchanged, since the Middle Ages. They provide a fascinating link with the live sounds of the past, missing in all other forms of evidence. Our knowledge of medieval music-making is immeasurably richer through the continued existence of the Arab lute, the fiddles of the Balkans, the shawms of Turkey and the Middle East, and the many other survivals mentioned or illustrated in this book.

### 3. ICONOGRAPHICAL EVIDENCE

Medieval and renaissance artists have preserved a wealth of information about musicians and their instruments in countless carvings, statues, paintings, manuscript illuminations, and woodcuts. Such evidence must be treated with great care. The stylization of medieval art often obscures playing techniques and details of size and construction, whilst throughout the Middle Ages and Renaissance conventions of classical and religious symbolism governed the work of all artists to a considerable degree. The most obvious instance is the dazzling variety of musical instruments shown in the hands of angels by religious painters of the fourteenth and fifteenth centuries. Such angel concerts belong not to this world but to paradise and they bear little relation to contemporary church-music practice, where the emphasis was on *a cappella* singing. For an illuminating study of this subject the reader is referred to Emanuel Winternitz's *Musical Instruments and their Symbolism in Western Art* (Faber, London 1967).

### 4. LITERARY EVIDENCE

Whilst literary references to musical instruments are numerous, writers, like artists, were affected by prevailing conventions. In French pastoral poems of the Middle Ages, for example, the classical association between shepherds and their pipes leads to an extraordinary emphasis on wind instruments, quite at variance with the dominance of stringed instruments in the real musical life of the time. In one study of 184 poems,[3] only three out of 104 instrumental references are to stringed instruments.

### 5. ACCOUNTS OF PERFORMERS AND PERFORMANCES

Eye-witness accounts of music-making are regrettably rare before the sixteenth century: if only there had been a medieval equivalent of Dr Burney how enlightened our knowledge of performance practice would be! A fascinating amount of information has been assembled by Werner Bachmann in chapter IV of *The Origins of Bowing* (Oxford University Press, London 1969) and it reveals that versatility was taken for granted. The medieval minstrel of *Les deux Bordéors ribaus* says: 'I shall tell you what I can do: I am a fiddler, I play the bagpipe and flute, harp, chifonie and giga, psaltery and rote, and I can sing a song as well.'[4] The ability to sing and double on instruments of such different types may surprise us today but it is echoed by William Kemp's praise of the Norwich Waits in 1600: 'Who, besides their excellency in wind instruments, their cunning on the viol, and violin: their voices be admirable, every one of them able to serve in any cathedral church in all Christendom for quiristers.'[5]

Although concerts of early music today tend to feature fairly small combinations of performers, special occasions evidently demanded forces of orchestral proportions. At the celebrations at Westminster in 1306 over sixty instrumentalists are listed as taking part[6] and the magnificent banquet known as the Feast of the Pheasant[7] held at Lille in 1454 featured a wide variety of colourful ensembles including twenty-eight musicians inside a huge pastry castle. During the Renaissance such court extravaganzas became more common and are regularly chronicled.

### 6. THEORETICAL WORKS AND TUTORS

Medieval theorists, following Greek practice, were more concerned with the academic and philosophical aspects of music than with prac-

tical details, and references to instruments and their use are tantalizingly scarce. The first substantial account comes in the treatise *De Inventione et Usu Musicae* written in about 1487 by Johannes Tinctoris (1445–1511). Even he includes only those contemporary fifteenth-century instruments which he could confidently derive from classical antiquity.

Information is more plentiful when we reach the sixteenth century. *Musica getutscht* (Basel 1511) by Sebastian Virdung is the first known instrumental tutor, dealing especially with keyboard instruments, the lute, and the recorder. Martin Agricola re-worked Virdung's material in his *Musica instrumentalis deudtsch* (Wittenberg 1528) and more specialized tutors followed, such as those by Sylvestro Ganassi for recorder and viol. The most informative and practical of renaissance writers on instruments is the German composer Michael Praetorius (1571–1621). The second volume of his treatise *Syntagma Musicum* (Wolfenbüttel 1618–19) is entitled *De Organographiia* and deals in fascinating detail with all the instruments of the day. The third volume of *Syntagma Musicum* contains a mine of information about contemporary instrumental practice. Finally, Marin Mersenne (1588–1648) devotes a substantial part of his *Harmonie Universelle* (Paris 1636) to instruments, and although he clearly lacked much of Praetorius' practical knowledge, his treatment is encyclopedic.

### 7. PAYMENTS AND INVENTORIES

Besides giving precise information as to who played what, where, and when, accounts of payments to musicians make absorbing reading, underlying the menial status of much of the profession and its inherent insecurity. Even musicians on a municipal or royal pay-roll often found their wages in arrears, whilst freelance itinerants were regularly classed with rogues and vagabonds. For a study in depth of one particular period, the reader is referred to Walter L. Woodfill's *Musicians in English Society from Elizabeth to Charles I* (Princeton University Press, 1953; reprinted Da Capo, New York 1969), and for lists of musicians employed in the English royal household to Henry Cart de Lafontaine's *The King's Musick* (Novello, London 1909; reprinted Da Capo, New York 1973).

A number of important inventories exist from the sixteenth century onwards, listing instruments belonging to various courts and households. Amongst the most valuable are the Henry VIII Inventory[8] and the Cassel Inventories.[9]

### 8. THE MUSIC ITSELF

In the days when composers wrote for the present rather than posterity and musicians performed what was, stylistically speaking, a very narrow range of music, it was unnecessary to write down everything relating to performance. Consequently, pieces with specific instrumentation are rare before 1600, though some unusual examples will be quoted during the course of the book. The only instruments which acquired an extensive repertoire of their own were the keyboard and lute families, and to a lesser extent the viol. This was the result of the use of tablature, a type of notation specifically designed for the instrument concerned.

Apart from the earliest keyboard tablatures, virtually the only purely instrumental music to have been preserved from the Middle Ages is monophonic dance music: the surviving *estampies* and *saltarelli* must represent a tiny part of a vigorous but largely unwritten tradition, governed by memory and improvisation. The principal role of instruments in art music was an accompanying one: to support the human voice in the song forms of the day – the ballade, virelai, and rondeau – though instrumental arrangements of these forms must surely have been made too. The restricted compass of medieval music made many different sizes of the same instrumental type unnecessary, and most instruments seem to have existed as a single basic size, with many variants. The independent lines of medieval polyphony suggest the use of contrasting instrumental types in an ensemble, rather than a uniform sonority, and much of the evidence already cited supports this.

With the Renaissance came the development of instrumental polyphony and the 'consort' principle. To cope with the demands of a new musical style, makers produced instruments in soprano-to-bass sets following the different categories of the human voice which composers began to distinguish clearly during the fifteenth century. But whilst the typical 'consort' of the Renaissance was a family unit, heterogeneous ensembles were popular too. The development of instrumental music greatly benefited from the start of music printing, pioneered by Petrucci in 1501 and followed by Attaingnant, Susato, Ballard and Le Roy, and many others. The quantity of instrumental music published during the first century of music printing is staggering: readers are referred here to Howard Mayer Brown's exhaustive survey *Instrumental Music printed before 1600* (Harvard University Press, Cambridge, Mass. 1965). A comparison of its contents with those of the inventories mentioned above reveals an apparent anomaly. The vast majority of music published is for strings (mostly lute) and keyboard, yet in the inventories it is the wind instruments which predominate. The explanation is a social one. Wind players were mainly professionals whilst for commercial success music publishing needed to appeal to the amateur market. And amateurs, both courtly and middle class, generally preferred strings. Playing the lute or virginals was an infinitely more decorous pastime than blowing a crumhorn or rackett and the gentle sounds of renaissance stringed instruments were ideally suited to domestic music-making.

It might be argued that this book omits what was the most important instrument of all in medieval and renaissance times: the human voice. Amongst theorists, composers, performers, and listeners its supremacy was unquestioned, and its influence on the development of man-made musical instruments was profound. Whether they were accompanying singers, doubling voice parts, or even replacing them entirely, instruments were measured against the human voice. Wide though it is, the spectrum of sound provided by early instruments can be seen as being made up of different facets of vocal timbre. And there was no doubt that the instrumentalist's job was to imitate the human voice as best he could. In the preface to the first recorder tutor, the *Fontegara* published in 1535, Sylvestro Ganassi shows clearly where his priorities lie. His opening remarks may be quoted by way of a *caveat* to this whole book:

'Be it known that all musical instruments, in comparison to the human voice, are inferior to it. For this reason, we should endeavour to learn from it and to imitate it . . . just as a gifted painter can reproduce all the creations of nature by varying his colours, you can imitate the expression of the human voice on a wind or stringed instrument . . . I have heard that it is possible with some players to perceive, as it were, words to their music; thus one may truly say that . . . only the form of the human body is absent, just as in a fine picture, only the breath is lacking.'[10]

# Part 1: The Middle Ages

*Music and Her Attendants*. Fourteenth-century Italian miniature illustrating the *De arithmetica* of Boethius. Paying homage to the central figure of Music, who is playing a portative organ, are musicians with examples of all the principal instrumental types of the Middle Ages: above her, fiddle, psaltery, and lute; beside her, tambourine and clappers; below her, bagpipes, shawm, nakers, and trumpets. The choice and arrangement of instruments has evidently been made with great care. Loud and soft instruments are separated from one another, and the selection features the most respected instruments of each type. The only surprising omission is the harp. (Biblioteca Nazionale, Naples: MS V A 14)

# 1 Woodwind

Medieval woodwind instruments offer a clear example of the 'soft' and 'loud' categories of music which Europe inherited from the East. Most of the reed instruments were loud and used mainly out of doors, whilst the intimate sound of the flute types was more appropriate indoors. The rules were not hard and fast, however. We know shawms were occasionally used in church, bagpipes found their way into soft ensembles, and the pipe and tabor and the military fife were regularly used in the open air.

Over details of pitch and range, it is impossible to be precise and in any case there was no standard type of each instrument but rather a whole series of regional variations. But it seems fairly safe to assume that most of the woodwind instruments on which overblowing was possible (all except panpipes, bladder pipes, and some bagpipes) had a range of roughly a diatonic octave and a half. Some chromatic notes, though certainly not all, could be obtained by cross fingering, but the bagpipes, bladder pipes, double pipes, and tabor pipes must have been very limited in this respect.

## Reed instruments

### The shawm

It is surprising just how *different* medieval instruments can be from any of their modern descendants. The shawm, derived from the Latin word *calamus* meaning a reed (hence also the French *chalemie* and *chalemele* and the Spanish *chirimia*), was the chief double-reed instrument until the seventeenth century. Yet who would suspect, listening to the intimate and seductive tone of the orchestral oboe today, that it was the offspring of such an aggressive outdoor parent? Of all medieval instruments the shawm is the wildest and most extrovert. Judging by survivals as far apart as Morocco and China, its tone was brilliant, piercing, often deafening. In folk music it is still used with other loud outdoor instruments such as trumpets and drums, and this was the case in the Middle Ages too. Even today in countries such as Turkey it is still possible to earn your living as an itinerant shawm player. In Istanbul it is a regular occurrence to hear a shawm and drum playing in the streets. The shawm player walks slowly in front, cheeks puffed out, blowing incessantly without pausing for breath. He is using the same technique as that employed by glass-blowers: the pressure from his cheeks helps him to blow *out* through his mouth whilst breathing *in* through his nose at the same time. Behind him comes the drummer playing on a *davul*, which is rather like a small bass drum. The player uses two sticks: a big spoon-shaped one for the basic beat and a thin double-ended stick for elaborate cross-rhythms. And at the same time he manages to pick up the money which people throw as they pass by.

It is fortunate that there are so many folk survivals of the shawm since they can teach us much about the instrument's history. Ensembles of shawms, trumpets, and drums formed the typical Saracen military band during the time of the Crusades. The noise must have been shattering, particularly when it assailed the ears of the early crusaders to whom such instruments were something of a novelty. The shawm is probably a Mohammedan invention and is said to have been developed in Baghdad during the time of the Calif Harun-al-Rashid (763–809).[1] Whilst the scholar Curt Sachs put the invention at least some 600 years earlier, in the second century AD,[2] it seems fairly certain that the shawm spread into Europe from the east, as a result of the Crusades, the trade through Constantinople, and the Moorish occupation of Spain.

The typical oriental shawm is a keyless instrument a foot or so long with seven finger-holes and a thumb-hole. Its essential features are its double reed and expanding conical bore. Although the wide flared bell is the instrument's most recognizable feature it makes comparatively little contribution to the tone or volume. Whilst the length and shape of the bore govern the pitch, it is the small *reed* and the way it is used which account for the shawm's amazing carrying power, helped in performance by the way many folk players blow the instrument upwards in the manner of a jazz trumpeter. A cylindrical section of softish reed, such as maize, is flattened out and squeezed into a waisted shape. It is mounted on a metal staple and is not controlled by the lips at all, but just by breath pressure. The player presses his lips against a metal disc at the base of the staple,

taking the entire reed inside his mouth.

The earliest medieval shawms in Europe were presumably very similar to their Eastern counterparts. From the twelfth century onwards the shawm starts to appear regularly in illustrations and carvings and we may assume that it continued to fulfil the same sorts of functions as it had done in the east: playing a principal part in military and ceremonial music, processions, and dance music. A typical literary reference comes in the fourteenth-century English romance *Sir Degrevant*, linking the shawm with trumpet and drum:

With the trompe and with nakere
And the scalmuse clere.[3]

By this time the European shawm had emerged in a rather different form from that of its oriental parent. The disc had been replaced by a pirouette and the nature of the reed and embouchure had changed (see chapter 6, page 40). Larger sizes were developing too. Whereas the earlier type of small shawm operated in the upper part of the treble stave descending to somewhere near F above middle C, the larger type of shawm went an octave or more lower. During the fourteenth century it acquired the separate name of *bombard* or *bumbard* (French *bombarde*, German *Pumhart*, and various other corruptions) from the Latin *bombus*, meaning drone or buzz. The word was apparently taken over from an artillery piece of the same name, and first occurs in the sense of a musical instrument in 1342.[4] In 1376 *grosses bombardes* were described as 'new', and in 1453 we find a *chalemie appelée bombarde* (a shawm called bombard).[4] In his *Confessio Amantis* (1393)

Gower actually distinguished the two types: 'the sounde of bumbarde and of clarionne with cornemuse and shalmele . . .'[5]

In a manuscript of about the same date, containing music by Hermann, Monk of Salzburg,[6] there are simple polyphonic compositions in which the lowest part is marked *der pumhart*, a rare medieval instance of specified instrumentation. At a time when there was rather a shortage of sustaining instruments of tenor pitch, the bombard must have been very useful for coping with the tenor parts in the chansons and motets of Machaut, Landini, and their contemporaries. Although opinion diverges on this point – the participation of the shawm in polyphonic music – both iconographical and literary evidence do suggest a wide and varied use of the instrument. It is particularly interesting that shawms were certainly used on occasions in church, not only ceremonially as when in 1235 the Abbot of St Albans was received 'with the minstrelsy of shawms', but also to double the voices of the choir.[7]

### Reed pipes and hornpipes

Whether it was playing martial music, dances, church music, or chansons, the sound of the shawm must always have been an intoxicating one. It belongs to the orgiastic tradition of reed instruments which begins with the Greek *aulos*, used to accompany the dithyramb in the wild rites of Dionysus, and continues with the jazz saxophone and clarinet of our own day.[8]

The precursor of all these is the simple reed pipe in which reed, mouthpiece, and finger-holes are all fashioned out of the same short length of cane. In most parts of the world where suitable cane is grown, these reed pipes are still common. Greek, Spanish, and Arab shepherds alike while away their time by making and playing these most primitive of reed instruments. A section of cane is cut leaving a knot at one end. Four or five evenly spaced finger-holes are burned out with a hot wire or nail, and the single reed is made by slicing out a small tongue, shaving it down but still leaving the base attached to the knot. And so it must have been throughout the Middle Ages and long before.

This straightforward instrument has developed many variants including double pipes and the more sophisticated hornpipe. As a single instrument, this survived in Wales until the eighteenth century as the pibcorn (literally 'pipe horn'). The handsome example now preserved in the Welsh Folk Museum, St Fagans, near Cardiff, shows the three-sectional construction. The central section is of wood and two horns are attached to it, the larger one at the lower and acting as a bell, the other as a mouthpiece enclosing the detachable single reed which is inserted in the top of the pipe. Hornpipes of this kind thus qualify as the earliest type of reed-cap instrument, though the horn makes a much less satisfactory and less comfortable cap than that later devised for the crumhorn and its relatives. Hornpipes must have been fairly common in Europe in the early Middle Ages. A Saxon vocabulary of the eighth century mentions one made of bone – the *swegelhorn*.[9] Double hornpipes were probably more common than the single variety, often minus one of the horns. All in all, single-reed instruments seem to have occupied a more important place in medieval music-making than they are generally given credit for. Nor was their use necessarily restricted to popular music if the Beauchamp window in St Mary's Church, Warwick, is anything to go by. The beautiful stained glass panels (designed in 1447) show an angelic consort in which single and double hornpipes are mixed with instruments of serious music-making such as the cornett, harpsichord, organ, and clavichord.[10]

### Bagpipes and bladder pipes

Features of all the instruments described so far are to be found in the widely differing forms of bagpipe. No other medieval instrument can claim such widespread and continuous use *since* the Middle Ages: Scotland, Ireland, France, Spain, Italy, Bulgaria, Czechoslovakia, Hungary, Poland, and Egypt are some of the countries in which distinctive varieties of bagpipe are still flourishing. Information about the instrument is voluminous and readers who would like more detail than the scope of this book permits should consult the authoritative works on the subject by Anthony Baines and Francis Collinson.[11]

Although the origins of the bagpipe are unknown, its history goes back long before the Middle Ages and it must have started life as a rustic instrument. What more natural than for a herdsman who tended sheep or goats and

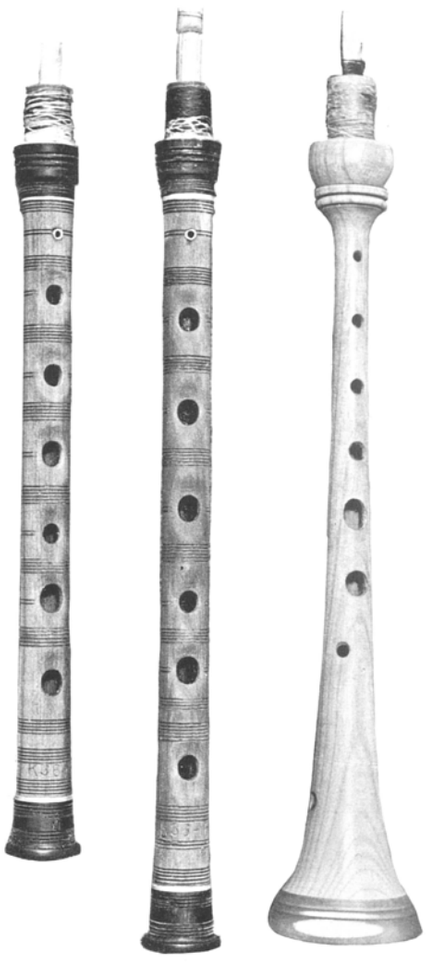
played a reed pipe to think of combining the two? Yet the earliest mention of the bagpipe is in the hand of an emperor. The Roman historian Suetonius relates how the Emperor Nero 'towards the end of his life . . . had publicly vowed that if he retained power he would at the games in celebration of his victory give a performance on the water-organ, the *choraulam*, and *utricularium*'.[12] The *tibia utricularis* is mentioned elsewhere, and the Greek Dio Chrysostom is specific. He says that Nero 'knew how to play the pipe with his mouth and the bag thrust under his arms'.[12] This royal association should not altogether surprise us, even though Nero's vow must have been in the nature of a penance. Throughout the Middle Ages the bagpipe was far from being a mere peasant instrument: it was heard and appreciated at all levels of society.

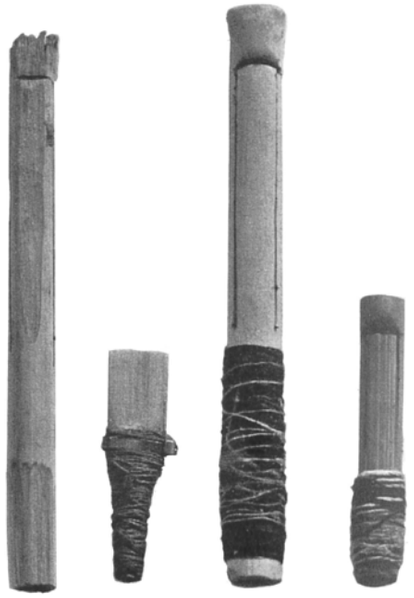
The reason for the bagpipe's development and enormous popularity is not hard to understand. The nature of any solo wind music, particularly medieval or folk dance music, makes a continuous sound desirable: yet this is impossible to achieve without the oriental breathing technique previously mentioned. The bag of the bagpipe solves the problem: the player can keep up the flow of air by squeezing the bag with his arm whilst he takes a breath to renew the air supply. The most common material still used for making the bag is the complete skin of some suitable animal such as a sheep or goat. Its neck and front leg-holes are useful for attaching the instrument's various pipes, though the joints are reinforced with *stocks*. These are wooden sockets fitted into the holes and secured by binding the skin tightly round them.

Besides the bag and stocks, the only other features common to all medieval bagpipes were the mouthpipe and the chanter. The mouthpipe contains a simple device which allows the player to breathe. A round piece of leather hinged on to the bag end of the mouthpipe acts like a non-return valve. When the player blows air in, it opens; when he stops blowing, the pressure in the bag forces the flap shut. The chanter usually has seven finger-holes and a thumb-hole giving a basic octave-and-a-note scale plus a tuning hole or two at the bottom end. The medieval bagpipe chanter existed in two different forms, either cylindrical bore plus single reed – adapting the reed-pipe idea – or conical bore plus double reed, following the principle of the shawm. Horns were sometimes added to the end of the cylindrical chanter after the manner of the hornpipe. Overblowing is only possible on pipes with conical chanters: modern Spanish players increase the pressure on the bag to extend the range two or three notes up into the second octave, but how far back this practice goes is uncertain.

It may seem surprising that the drone – to us the most characteristic feature of the bagpipe's sound – was not ubiquitous in the Middle Ages. Although drones were certainly in common use from the thirteenth century onwards, they were by no means universal. It is likely that the earliest forms of the instrument were droneless, like the simple bagpipe to be heard in the nightclubs of Cairo to this day. The drone pipe is always cylindrical[13] and sounded with a single reed. In order to permit accurate tuning with the chanter (normally two octaves below the chanter's key note) the drone is made in two or more sections, so that the player can sharpen or flatten it by adjusting the length. The miniatures in the thirteenth-century *Cantigas de Santa María*[14] manuscript include bagpipes with two drones but this seems to have been unusual until renaissance times.



Alternative Bulgarian chanters (cylindrical bore) and Spanish chanter (conical bore). During the Middle Ages the conical chanter became the standard European form.



Bagpipe reeds (*l* to *r*) Spanish drone (single) and chanter (double), Bulgarian drone (single) and chanter (single).

The bagpipe made an ideal instrument for solo dances and monophonic music, but it seems to have taken part in polyphonic music too. Guillaume de Machaut (*c.*1300–77) includes bagpipes in a rare and rather baffling clue to the instrumentation of his own music. In *Le Livre du Voir Dit* he suggests that his three-part ballade *Nès que on porroit*[15] may be played on the organ, bagpipes, or other instruments and that 'this is its very nature'.[16] If only Machaut had been more specific! Only the tenor part of the piece, with a range of a diatonic octave, seems at all negotiable on the bagpipe and even here the rests present a bit of a problem. With its limited compass the use of the bagpipe in polyphonic music remains quite a mystery. The existence of a drone removes the possibility of any change of keynote, and even without a drone there is the problem of articulation. You cannot tongue a note on the bagpipe because the air reservoir in the bag acts as a barrier between tongue and chanter. Instead the effect of articulation is achieved by some kind of 'gracing': at its simplest this means sounding another note with a quick flick of the fingers which has the effect of a very short acciaccatura. We simply do not know what sort of gracing medieval bagpipers used, but it may have sometimes been quite elaborate, as in Highland bagpipe music today, where gracing has become an art as subtle and varied as the ornamentation of the French *clavecin* composers such as Rameau and Couperin.

Although it is frequently pictured or listed in the company of other instruments (including an ensemble of twenty-eight at the Burgundian *Feast of the Pheasant*[17]) it is difficult to see how the bagpipe could have ever been a satisfactory instrument for polyphonic music. As so often the medieval theorists give us no practical help. The bagpipe is 'above all other instruments' says Jerome of Moravia (*c.*1250) echoing what John Cotton said a century before.[18] Yet the existence of the *bladder pipe* from the thirteenth century onwards suggests that whatever the bagpipe's status, players may have been trying to solve some of the problems just mentioned. In essence, the bladder pipe seems to have

Bladder pipe from Virdung's *Musica getutscht* (1511).

been an attempt to have it both ways: to combine the bagpipe's continuous air flow with an instrument which could stop and start more easily, and on which some kind of tonguing and articulation may have been possible. Instead of a large animal skin which requires arm pressure to make it work, the bladder pipe employs an elastic animal bladder which will expel a certain amount of air down the pipe just by its own elasticity. The air reservoir is much smaller than on the bagpipe, so the player would have had to snatch a quick breath when necessary as opposed to the more leisurely breathing possible on the bagpipe. The bladder pipe continued in use up to the sixteenth century, even after the crumhorn had become popular. Virdung includes it in his *Musica getutscht* (1511) under the name *Platerspil*. The instrument had already taken various forms: the *Cantigas de Santa María* manuscript shows a curved single bladder pipe and a straight double one. Although the curved instrument, like Virdung's, is apparently made out of a solid piece of wood in the manner of a crumhorn, the shape must have come in the first place from a horn bell added to a straight tube as on the hornpipe. This feature is preserved on a rare Polish shepherd's instrument, apparently the only real modern survival of the bladder pipe.[19] It is curious that whilst the bagpipe has gone from strength to strength, the bladder pipe has almost entirely died out.

**The douçaine**

For all the reed instruments so far described there exist both folk music survivals to tell us what they sounded like, and medieval pictures or carvings to tell us what they looked like. No such help is forthcoming for the *douçaine*, the most mysterious of all medieval instruments. It is regularly mentioned in European literature of the thirteenth, fourteenth, and fifteenth centuries in various spellings including *dulçema* (Spanish) and *douchaine* (Low German). Machaut mentions the *douceinne* in the *Remède de Fortune*, and in the fourteenth-century poem *Les Échecs amoureux*, *douchaines* are described along with flutes as being very soft and very pleasant.[20] Piecing together the scanty information available has led different scholars to varying conclusions:

'... the soft oboe' (Sachs)[21]

'... just a suspicion that it might have been a type of flute' (Hayes)[22]

'... we cannot altogether rule out another possible answer, namely that the instrument was a kind of shawm' (Baines)[23]

The most specific information comes in the *De inventione et usu musicae* (*c.*1487), one of the theoretical works of Tinctoris, who classes the *dulcina* as a type of *tibia* (reed instrument). He distinguishes it from the shawm (*celimela*) which is a perfect instrument on which any kind of composition can be played. 'On the other hand that *tibia* called the *dulcina*, on account of the softness of its sound, has seven holes in front and one behind, like a *fistula* (recorder). Since not every kind of piece can be played on it, it is considered to be imperfect.'[24]

In other words the douçaine has the restricted compass characteristic of cylindrical bore reed instruments. It was certainly soft – the adjective is several times applied to it – and it certainly had a reed according to Tinctoris. If its bore was cylindrical, the douçaine must very probably have operated at tenor rather than treble pitch. Pitch, compass, and volume would have thus made it ideal for medieval tenor parts which are often limited to an octave and a note in range. What is unclear is the nature of the reed (single or double) and the technique used for playing it (direct contact or some kind of reed cap), and unless more evidence comes to light, it seems extremely unlikely that the mystery will be satisfactorily solved.

## The flutes

Medieval instruments of the flute type employed two quite different methods of sound production:

1. blowing across a round mouth-hole, as on the panpipes or transverse flute,
2. blowing into a whistle mouthpiece, as on the recorder or flageolet.

It is clear that the word *flute* and its variants were used indiscriminately for both types: Machaut distinguishes the *flaustes traversaines* (transverse flutes) from the *flaustes dont droit joues quand tu flaustes* (flutes that you hold straight when you play).[25] Confusion over flute nomenclature persists to this day: there is still a surprising number of people, including conductors, who are not aware that during the baroque period flute or *flauto* specifically meant recorder and *not* transverse flute. But whereas baroque composers were precise about their terminology, medieval composers and writers were not. Machaut also mentions the *Flauste brehaingne*[26] (literally 'sterile flute'), the *floiot de saus*[26] (osier flute), and the *ele*[27] (perhaps a shortened form of *frestel*). Other literary sources mention the *flajol, flajolet, floyle, frestel, fletsella, muse d'ausay*, and *estiva* which different authorities have all identified as flutes of some kind.

It is doubtful if we shall ever succeed in sorting out all the various names into specific flute types nor is it likely that many of the names had a single specific meaning. In any case their number is slight compared to the number of flute types which existed in the Middle Ages, each subject to almost infinite regional variation.

Flutes were exceedingly popular and ranged from simple peasant instruments to those of highly sophisticated courtly society. Especially with the whistle types the same situation applies today: there is scarcely a country in the world which cannot boast its own whistle instrument of some kind.

**Panpipes and transverse flutes**

Although these two instruments are linked by their method of sound production, their history, appearance, and playing technique could scarcely be more different. The origin of both is a simple bamboo tube stopped at one end, open at the other. But whilst several pipes of different length were bound together and sounded vertically to make the panpipes, a single tube held horizontally became a transverse flute when finger-holes were added, together with a mouth-hole near the stopped end. The transverse flute may well be regarded as a rationalization of the panpipe principle, and therefore a later development. Both instruments have a history stretching back long before the Middle Ages. Panpipes are most familiar to us from illustrations and literary references in classical times: the name comes from the association of the instrument with the mythological god Pan. Greek and Roman artists show the orthodox form of the instrument as seven lengths of cane bound together. Similar representations were common in Europe throughout the Middle Ages, Renaissance, and Baroque, but this should not lead us to suppose that the panpipes played an equally significant part in music-making during all this time. Even in Greek times the panpipes were unimportant compared to the *aulos* or the *kithara* and for much of the post-classical period they existed as rustic or popular instruments only. When we find the panpipes played side by side with the *real* instruments of music in late medieval or renaissance art their presence is usually of purely allegorical or symbolic significance.[28]

As an instrument of practical music-making the heyday of the panpipes was the time of the troubadours and trouvères (eleventh to thirteenth centuries). During this period the instrument is represented in a variety of forms which differ considerably from the orthodox classical type, both in the number of pipes and the method of construction. A twelfth-century manuscript, now in St John's College, Cambridge,[29] illustrates the solid type of construction in which the pipes are drilled out of a flat piece of wood. Solid pottery construction was used too: all the surviving medieval panpipes are ceramic with the number of pipes varying from five to eleven.[30]

Canon Galpin also mentions 'trustworthy examples' of the panpipes constructed in semicircular shape from medieval manuscripts and instances one of the early eleventh century.[31] This curved shape encourages greater fluency on the instrument and is found on the most sophisticated modern survivals, such as the Romanian *naiu* with twenty-six pipes. Virtuosi such as Gheorghe Zamfir have achieved a technical and expressive mastery of

the instrument which any woodwind player must envy. His repertoire of solos, often borrowed from the violin, includes brilliant display pieces demanding phenomenal agility, staggering breath control, and double and triple tonguing of great rapidity. Equally impressive are the slow mournful pieces in which the panpipes can produce every nuance of feeling by varied tone colours, vibrato control, and a characteristic 'droop' in pitch – sometimes by as much as a semitone – achieved by altering the angle of embouchure.

The style of medieval panpipe playing must have been simpler and less sophisticated, perhaps resembling that used by the South American Indians today. The number of pipes was more limited, giving a short diatonic range ideal for dance music or the more straightforward troubadour and trouvère melodies. This simple *chanson à refrain* could be played on a six-pipe instrument.

Anonymous thirteenth-century chanson à refrain.

But once the development of polyphonic music demanded the use of accidentals outside the basic mode, the panpipes' usefulness was on the wane.

The rise of the transverse flute seems more or less to correspond with the decline of the panpipes. To regard one as a direct replacement of the other in music-making would be an over-simplification, but it is true that, whilst maintaining some of the panpipes' hollow tone-quality, the cylindrical six-holed flute can manage most of the important chromatic notes by cross fingering or occasionally half-holing. Added to that, the flute must have been capable of a good two-octave range, though whether medieval players used it all we don't know. The use of the keyless flute in the classical music of China and India testifies to the wide range and advanced technique which are possible on the instrument.

Besides a history in the Far East which extends to remote antiquity, the flute was also known to the Etruscans, the Egyptians, and the Greeks. It was through Byzantine influence that the flute finally made its way into central Europe in the twelfth century. Important evidence comes from the encyclopedia *Hortus Deliciarum* (late twelfth century) where the flute is given the German name *swegel*.[32] The instrument became something of a German speciality and the expression *German* flute is found off and on for the next 800 years as a means of distinguishing the *transverse* flute from whistle types.

The Germans developed two distinct uses for the flute: courtly and martial. It was evidently a popular instrument amongst the Minnesänger (the German equivalent of the troubadours) and we find the flute depicted alongside other courtly instruments such as the fiddle and harp. From the thirteenth century onwards it also becomes associated with the drum as a military band instrument, although it was not until the following century that the flute, in either role, became common outside Germany.

### Six-holed pipe and double pipes

More examples of whistle flutes have survived from the Middle Ages and earlier times than of any other kind of instrument. Frederick Crane[33] lists no less than 140 of them in a great variety of forms as well as numerous simpler whistle types without finger-holes. Their method of sound production is familiar from the modern recorder and penny whistle, and their essential features are:
*the lip* cut near the top of the tube,
*the fipple* (usually a block of wood) inserted in the mouthpiece,
*the windway:* a narrow channel above the fipple through which the breath is directed against the edge of the lip to produce the sound.

The whistle mouthpiece seems an ingenious idea compared to the other flute types. It is easy to see how primitive man could have stumbled on the principle of the panpipes by idly blowing across a stopped piece of cane, but it is more difficult to imagine how the whistle mouthpiece developed by chance. Yet the history of the whistle mouthpiece seems to go back almost as far as that of *homo sapiens*: the earliest whistle instrument so far discovered dates from the Upper Paleolithic period.[34]

The variety of whistle flutes in medieval times is matched by the many forms found today. The most common material is still cane or bamboo, used for rustic instruments, which are as easily fashioned as the reed pipes. It is presumably what Machaut meant by his *floiot de saus* (osier flute) and in a typical pastoral poem of the thirteenth century the trouvère Colin Muset describes the making of the instrument.

L'autr'ier en mai, un matinet,
M'esveillerent li oiselet,
S'alai cuillir un saucelet,
Si en ai fait un flajolet.[35]
(The other day on a May morning I was woken up by the little birds. I went out to cut a reed and have it made into a *flajolet*.)

The number of finger-holes no doubt varied, but six holes (*ie* no thumb-hole or little-finger-hole) seems to be a common standard today.

Although Colin Muset and others used the word *flajolet* we should perhaps avoid translating it literally as *flageolet*, or using the word at all as an umbrella term for whistle-flutes. The special characteristic of the flageolet proper is *two* thumb-holes, and the instrument was not standardized until the end of the sixteenth century when the French flageolet was 'invented' by Le Sieur Juvigny.[36] Besides four finger-holes and two thumb-holes, the later seventeenth-century design of the flageolet incorporated a mouthpiece cap containing a sponge to absorb the moisture from the player's breath. This instrument remained popular, largely as an amateur instrument, until the nineteenth century. Unfortunately English makers such as Bainbridge and Potter then developed a new instrument, retaining the special mouthpiece and the name 'flageolet' but dropping the flageolet's special feature, the two thumbholes. Since then, confusion has multiplied over what is, or is not, a flageolet and even some penny whistles are now sold under that name. If inflation has made the name 'penny whistle' obsolete, we should return to Mersenne's definition *la flute à six trous*[37] or the six-holed pipe.

Double pipes were popular too, presumably because a solo on them could make more impact than on a single pipe, though the classical tradition of double *auloi* may have encouraged an excessive number of representations in art and sculpture. Certainly double pipes do crop up in some rather unlikely playing positions. The Pied Piper figure in Simone Martini's fresco *L'investitura di San Martino* looks in great

Detail from *L'investitura di San Martino* by Simone Martini (1284–1344). (Basilica di San Francesco, Assisi)

difficulties: he seems to have more finger-holes than he can cope with and some balance problems too, since the right-hand little finger is being used to support the instrument. It would all be much easier if the pipes were *parallel* and fastened together. Folk instruments confirm that this must have usually been the case, and help us to distinguish two basic types of double whistle-flute. In both the two pipes are to some extent unequal. On one type there is a melody pipe plus a drone pipe; it is easy to see how the bagpipe encouraged this sort of thing. The Yugoslav *dvojnice* is a more sophisticated instrument carved out of wood, elaborately decorated and designed so that the two pipes can play together mostly in thirds.[38] Medieval double pipes of this kind were more likely to have been designed for playing in consecutive fourths or fifths. A wooden example excavated at Christ Church, Oxford,[39] has a thumb-hole and four finger-holes in each pipe. The lowest note of the right-hand pipe is c″, that of the left g″. Such an arrangement makes possible the playing of simple part music.

**Pipe and tabor**

An even more common addition than a second pipe was some kind of percussion instrument: pipe and tabor, pipe and tambourin (stringed drum), even pipe and triangle were all used, though the pipe and tabor was by far the most popular. When Jehan Erars wrote:

Guis dou tabor au flahutel
Leur fait ceste estampie[40]
(Guy with his tabor and pipe plays them this *estampie*)

he was describing a one-man-band which is ideal for dance music: the drum giving the beat and the pipe playing the melody. The technique required of the player is rather specialized, involving three distinct skills which must be co-ordinated, yet independent.

Modern folk players always *lead* with the drum, holding the stick loosely in the right hand and often allowing it to beat quite intricately decorated rhythms. The tabor itself (a kind of snare drum: for more details see chapter 5, page 32) is slung in various ways on the left-hand side of the body: it can be secured to the waist, slung over the left arm, or even, in the case of a very small tabor, suspended from the little finger. The left hand holds the tabor pipe: a long slender cylindrical pipe with holes for two fingers and thumb. The narrow bore is important because it enables the player to overblow easily and obtain not only the second harmonic (overblowing at the octave) but the third, fourth, and fifth harmonics (overblowing at the 12th, 15th, and 17th respectively). Whereas the basic scale of all the instruments so far described consists of their *fundamental* notes, the fundamentals of the tabor pipe are very weak and not used at all. Instead the basic scale starts with the second harmonics, enabling a mere three holes to produce a complete diatonic scale. The following chart makes clear how fingering and breath pressure are combined. Thus the pipe and tabor combines single-stick percussion technique, woodwind fingering, and the employment of the harmonic series otherwise peculiar to brass instruments. It came into regular use during the time of the troubadours: a Polish tabor pipe survives from the second half of the eleventh century[39] and pipe and tabor players are regularly illustrated from then onwards.

During the Renaissance the tabor pipe seems to have been quite a large and sturdy instrument like the Basque *chistu* or the 'alto' pipe supplied by the English Folk Dance and Song Society. Famous Elizabethan players included William Kemp and Richard Tarleton, two of the most famous comedians of the day. In 1599 Kemp danced a Morris dance all the way from London to Norwich, apparently accompanied by pipe and tabor as he went. By this time the pipe and tabor had fallen in social status from a court instrument to an instrument of the common people. Literary references link it with rustic merry-making and the maypole.

Thomas Weelkes's ayre beginning:

As a folk instrument, the English pipe and tabor just survived into this century, and with the revival of interest in our folk music and the work of the English Folk Dance and Song Society it is now once again a regular thing to see pipe and tabor players playing for Morris dancing, as they did in Elizabethan times. Abroad in France and Spain the Provençal *galoubet* and the Basque *chistu* continue a tradition which has flourished for 900 years.

**The recorder**

Amongst the variety of medieval whistle instruments the recorder only gradually emerged as the most useful and versatile type. Its tremendous popularity in later ages has tended to over-emphasize its place in medieval times, when its status was at best *primus inter pares* with the other instruments discussed in this section. In any case it is difficult to chronicle the early history of the recorder because of the problem of positively identifying what is and what is not a recorder in medieval art and sculpture. The essential features of the recorder are its beak-shaped mouthpiece and the number of its finger-holes: seven finger-holes plus a thumb-hole. But since its playing position is similar to that of so many other wind instruments it is often impossible to be sure whether a particular illustration depicts a recorder, another whistle type, or some kind of reed-pipe or shawm. The earliest portrayal which has been accepted as being of a recorder comes in a twelfth-century Psalter in the library of Glasgow University.[42] This is two hundred years before the word 'recorder' appears: the earliest reference to come to light so far occurs in the household accounts of Henry, Earl of Derby (later King Henry IV), for 1388 noting payment for a *fistula nomine Ricordo* (a pipe called a keepsake).[43] During the fifteenth century the word 'recorder' seems to have come into use in England, whilst on the continent the more general (and confusing) name 'flute' continued to be employed.

By this stage the recorder had developed a variety of sizes just as the shawm had. Whereas most early medieval whistle-flutes were probably fairly small and high-pitched like the surviving bone specimens,[34] by the fourteenth century there were almost certainly instruments which could go as low as middle C (the bottom note of the modern tenor recorder). The existence of a variety of sizes of late medieval recorder made them the most useful flute type when an ensemble was required. In 1385, at the marriage of the Duke of Burgundy with Margaret of Bavaria at Cambrai, the music for the Mass was performed by *molt brafs contres et flusteurs musicals* (excellent singers and flute players).[44] The likelihood is that the *flusteurs* were recorder players, who could cope with the different ranges of voice parts, doubling them an octave higher.

**The gemshorn**

All the instruments so far mentioned in this section possess a basically cylindrical bore. The only medieval flute type with a sharply tapering conical bore was the *gemshorn* (the German name means chamois horn) where the taper was unavoidable because of the natural shape of the animal horn. This gives the gemshorn a sweet, watery tone colour somewhere between a soft recorder and an ocarina. The history of the gemshorn is rather a puzzle. A large number of antler whistles have been found from the Bronze Age onwards, though their nature is disputed.[45] Yet the first clear illustration of the instrument is not found until Virdung's *Musica getutscht* (1511) where the horn is apparently cow or ox rather than chamois. The only surviving instrument, discovered by Curt Sachs, is generally similar though made of goat's horn and with six finger-holes instead of Virdung's four, together with a vent hole near the tip.[46] Agricola includes the gemshorn in the first edition of his *Musica instrumentalis deudtsch* (1528) but omits it from the final edition of 1549, suggesting that the instrument had by then fallen out of use. Praetorius (1619) and Mersenne (1635) mention the gemshorn only as an organ stop. *Lieblich* (lovely) is Praetorius' description of the sound.[47]

Since organ builders were already imitating the gemshorn by the mid-fifteenth century the instrument must have been quite common by then.[47] What is missing is some connection between the primitive medieval antler whistles and the more sophisticated gemshorn types of the early sixteenth century.

# 2 Keyboard

Although it would be misleading to describe all medieval instruments as 'crude' or 'primitive' as far as their *playing* techniques are concerned, it is true that the techniques involved in their *construction* are mostly straightforward. The absence of woodwind keys, brass valves, or the multiplicity of parts involved in violin-making is characteristic of the days when most players were also the makers of their own instruments. On the whole, musical instruments in the Middle Ages were not the masterpieces of mechanical ingenuity that many of them are today. So the extent to which keyboard instruments developed before the fifteenth century may seem surprising, since in order to function at all a keyboard instrument requires a mechanical action, a whole series of sound producers – either strings or pipes – and a degree of mechanization quite foreign to other types of instrument.

**The early medieval organ**

Of all keyboard instruments the organ is much the oldest. As with so many aspects of art and science the Greeks can claim credit for its invention and initial development. It was Ktesibios, a Greek engineer living in Alexandria, who built the first organ in history during the third century BC. Pliny the Elder described the invention as one of the wonders of the world[1] and its reputation has grown since, partly through a misunderstanding of its name *hydraulis* (from the Greek *hydor,* water, and *aulos* pipe). 'Water-organ' is the usual translation, a rather unfortunate one since it conjures up a fantastic vision of plumbing with water gurgling through the pipes: during the Middle Ages it was actually thought that the hydraulis had employed boiling water or even steam! In fact, water was simply used in order to provide stabilization of wind pressure. Nor does the sound appear to have been as loud and penetrating as has often been stated. Cicero describes the sound as a sensation which is as agreeable to the ear as the tastiest fish is to the palate.[2] For both the Greeks and the Romans the hydraulis was an instrument of private rather than public entertainment and the outdoor instruments which accompanied gladiator fights and acrobatic shows seem to have been the exception rather than the rule. Most important of all, the hydraulis established the principle of the keyboard – a series of levers, each equipped with a return mechanism, which were pressed down by the fingers to obtain the required series of notes.

During the fourth century AD the hydraulic mechanism was superseded by the introduction of bellows and the hydraulis gave way to the pneumatic organ. From this time onwards descriptions of the bellows' action are regularly coupled with accounts of the organ's devastatingly loud noise. 'It emits a strong sound through twelve bronze pipes so that it can be clearly heard everywhere within a thousand paces'[3] says one account of a fourth-century organ, worked by no less than fifteen 'smith's bellows'. The famous *Utrecht Psalter* of about AD 860 vividly illustrates the amount of elbow-grease required, although the instrument depicted is, in fact, a fanciful version of the ancient hydraulis. Four men are straining away on the long beams connected to the huge wind chests, beneath a rather diminutive array of pipes, whilst two monks encourage the men to even greater efforts. From England we have copious information about a gigantic organ installed at Winchester towards the end of the tenth century. According to the poetic account of the monk Wulstan there were four hundred pipes and twenty-six bellows requiring the efforts of seventy strong men who were:

Labouring with their arms, running with sweat,
Each urging his companions to force the wind up
With all his strength filling
The wind chest's vast cavity that it may rumble . . .
Like thunder, the strident voice assails the ear,
Shutting out all sound other than its own;
Such are its reverberations, echoing here and there,
That each man lifts his hands to stop his ears,
Unable as he draws near to tolerate the roaring
Of so many different and noisy combinations.[4]

Even allowing for poetic licence, Wulstan's long and detailed description is very informative and makes clear several important features of the large medieval church organ. Taking into account various sources of evidence, pictorial and literary, the nature of the large medieval church organ before the thirteenth century may be conveniently summarized as follows:

1. The pipes were of the 'flute' type, *ie* voiced with a lip like the recorder.
2. Instead of the keyboard developed on the hydraulis there were a series of *linguae* (tongues) or sliders which had to be pulled out and pushed in manually.
3. Because of this clumsy mode of operation, two players were often required, seated at the same manual and dividing the overall compass between them.
4. There were often more pipes than sliders (on the Winchester organ the proportion was ten to one).
5. When this was the case each note was produced by a simultaneous 'mixture' of different pipes, producing a variety not only of timbre but also of pitch. There were 'unisons' (sounding at the basic pitch), 'octaves' (sounding an octave higher), and 'quints' (sounding one or more octaves plus a fifth higher).
6. When a medieval organ had a number of different ranks of pipes, it still had only one basic sound, since there were no draw-stops to change the combination of pipes. These were not developed until the fifteenth century.
7. The spectrum of sound from top to bottom of the register was a changing one, since according to many illustrations all the pipes were of the same diameter. On later organs the diameter is proportionate to the length, so that the shortest pipes are narrow and the largest much broader.

However limited their musical scope the sound of these large organs was clearly impressive, but their precise function in church music is still a matter of debate. With all its secular associations from Greek and Roman times the organ was not entirely welcomed by the early Christian Church and its use was regularly questioned. 'Whence hath the Church so many Organs and Musicall Instruments? To what purpose, I pray you, is that terrible blowing of Belloes, expressing rather the Crakes of Thunder, than the sweet-nesse of a voyce?' So wrote Aelred, Abbot of Rievaulx in Yorkshire during the twelfth century (the translation is from William Prynne's *Histriomastix* published in 1633).[5] Yet there was a very obvious purpose to which organs could have been put during the twelfth century and that is doubling the voices of the choir or even replacing them entirely in the long sustained tenor parts which occur in the works by composers of the Notre Dame School. The huge organa of Léonin and especially Pérotin cry out for some kind of instrumental support[6] and it has been suggested that the whole practice of organum came from the organ in the first place. It must be remembered, however, that the Latin word *organum* meant any kind of instrument, not just the organ, and it cannot be established with any certainty that the cathedral of Notre Dame actually possessed an organ during the time of Léonin and Pérotin.[7]

**Portative organ and positive organ**

During the thirteenth and fourteenth centuries the trend in organ-building seems to have moved from the monstrous to the miniature. All the important developments took place on much smaller types of instrument on which it was possible to restore the delicate keyboard of antiquity, and it was for them that the earliest surviving examples of keyboard music were designed. The old custom of labelling the sliders with letters for each note of the scale led to the development of alphabetical organ tablature. It is not clear precisely when the clumsy slider movement was abandoned in favour of the keyboard, permitting an infinitely more sensitive finger technique, but the Belvoir Castle Psalter and other sources prove that the organ keyboard was well established by the thirteenth century, as was the practice of playing with both hands.

The change in emphasis in organ-building was certainly bound up with the changing role of the Church in political and social life. The image of the Church was becoming mercenary and corrupt, its authority was on the wane, and the process of decline culminated in the rivalry of the Papal Schism (1378–1417), during which two Popes vied for the position of God's highest representative on earth. Composers turned their attention to the court rather than the Church and there was a tremendous surge of interest in the composition of secular music. It is no accident that the earliest collections of keyboard music contain a high proportion of secular pieces: the dances in the Robertsbridge fragment[8] (*c.*1320) and the many settings of ballades, madrigals, and ballate in the Faenza Codex[9] (late fourteenth century). When Guillaume de Machaut referred to the organ as the 'king of instruments'[10] he was surely paying

tribute to its versatility as well as its virtuosity and to its ability to enhance every realm of music-making.

Virtuoso the organ certainly had become by the fourteenth century. The Robertsbridge and Faenza collections demand some nimble finger-work, especially from the right hand. Organ-playing was even becoming competitive. At a contest held in Venice, probably in 1364, the organ playing of Francesco Landini (*c.*1325-97) is said to have earned him a laurel wreath from the King of Cyprus, and although this has been disputed[11] Landini's skill as an organist is beyond doubt. One of the most charming compliments comes in a *novella* by Giovanni da Prato. 'After this story, the sun was coming up and beginning to get warm; a thousand birds were singing. Francesco was ordered to play on his organetto to see if the singing of the birds would lessen or increase with his playing. As soon as he began to play, many birds at first became silent, then they redoubled their singing and, strange to say, one nightingale came and perched on a branch over his head.'[12]

The *organetto*, usually known today as the portative organ, was one of the most popular instruments, regularly illustrated from the thirteenth to the sixteenth centuries. There are usually two rows of pipes giving a range of up to two octaves (one pipe to a note) and judging by the size of the pipes the lowest note must have been round about middle C. Some medieval illustrations (like the picture of Landini on this page) show a couple of much longer pipes at one end, perhaps to provide some kind of drone. The portative was of light construction and when supported by a sling could easily be carried about or played in procession. Its unique feature was the way the player provided his own air supply, using the right hand on the keyboard and the left hand for the bellows. And that was not the limit of the player's dexterity. According to the thirteenth-century *Roman de la Rose:*

Orgues i r'a bien maniables,
A une sole main portable,
Ou il-meismes soufle et touche
Et chante avec a plaine bouche
Motes, ou treble ou teneure . . .
(There are easily manageable organs that can be carried in the hand, the same person simultaneously pumping (the bellows), playing (the instrument), and singing aloud motets, either soprano or tenor . . .)[13]

Unlike the other types of organ, the portative was a monophonic instrument, suited to playing a solo dance or a single part in a chanson or instrumental piece. As with the larger organs, its keyboard was diatonic to start with, though by the end of the fourteenth century it had probably become more or less fully chromatic.

Detail showing the keys of the Halberstadt organ, from Praetorius' *Syntagma Musicum* (1619).

Although the 'great' church organ replaced its old slider mechanism with a version of the new keyboard it remained an unwieldy, clumsy instrument. During the fourteenth century additional keyboards were added to offer some variety of tone. On the organ completed in 1361 at Halberstadt Cathedral in Germany there were three manuals and a pedal keyboard, though this must have been unusual for the time. But in spite of the existence of twenty bellows worked by ten men, the compass was only twenty-two notes with fourteen 'naturals' and eight 'sharps'. The instrument was renovated in 1495, and Praetorius (1619) gives us a description of it and illustrates its keyboards. The clumsiness of the keys is clear enough: Praetorius even suggests that the lowest of the three manuals could be played with the knees. As for the sound:

'All was of a coarse mixture. This is evident from the . . . size of the clavier, which did not extend high enough for beauty, but produced a deep, coarse roar and a fearful growling to which the mixture pipes added an extraordinary loud noise, a terrible scream.'[14]

Such an instrument could demand strenuous physical effort from the player. When the wind pressure was enormous it might need the full muscular force of the arm to keep a key down. The playing technique was similar to that still used on the carillon today where each key is struck with the closed hand. With the clumsy action of some medieval instruments players must have occasionally resorted to a strong blow from the fist. The carillons – sets of bells played by means of one or more keyboards – were built in the Low Countries at the end of the Middle Ages, and their development is related to that of the large organ. In the fourteenth century in the Netherlands carillons were played with the feet as well as the hands,[15] no doubt because the player could exert more strength with his feet, and the existence of this technique may have encouraged the development of the organ pedal keyboard. What the Dutch writer Fischer said about carillon players in 1738 certainly applies to medieval organists too: 'A musician requires nothing more than a thorough knowledge of music, good hands and feet, and no gout.'[15]

Modern portative organ by Noel Mander. The pipes are graded in diameter, as on the renaissance portatives which have been preserved.

Whilst the 'great' organ remained in the Church's domain and the portative was used primarily for courtly entertainment, the 'positive', lying between the two types in size, was suitable for both Church and chamber music. It was larger than the portative, requiring two or three sets of bellows and an assistant to operate them; this enabled the player to use both hands at the keyboard. Longer pipes extended the compass downwards, and the typical positive had a basic 'mixture' sound of several pipes to one note. Although it was not 'portative' in the sense the organetto was, the positive could be moved about fairly easily. Larger instruments stood on the floor whilst smaller ones are often shown standing on a table. Of the three types of organ, the positive was the most versatile and though it survived as an independent instrument in its own right it also became incorporated in the 'great' church organ. Hence the names 'positive' and 'great', used since the Renaissance to describe two of the organ's manuals. In England the positive became known as the 'chair' organ, which has gradually become corrupted to 'choir' organ.[16]

**The hurdy-gurdy**

The first stringed instrument to which the keyboard principle was applied was the hurdy-gurdy, variously known as the *organistrum*, *symphonia* or *chifonie*, *organica lyra*, *armonie*, and *vielle à roue*. This last name (literally 'wheel-fiddle') explains one of the two processes of mechanization involved. The bowing action of the fiddle is replaced by a wheel cranked by a handle. The wheel, the outer rim of which is coated with resin, makes all the strings resonate at once, whether drone or melody strings, and provides a continuous sound. In the same way that the bag of the bagpipe avoids stopping for breath so the wheel of the hurdy-gurdy avoids changes of bowing. In addition the process of fingering is mechanized too, the same string being stopped at different points to produce the required scale.

The earliest evidence for the hurdy-gurdy in Europe dates from the first part of the twelfth century though, like the art of bowing, the principle may have been inherited from earlier experiments in the East.[17] By the time of the Notre Dame School (late twelfth century) the instrument was both widely used and highly regarded. From the thirteenth century onwards both construction and playing technique changed considerably. There are several interesting parallels with the development of the organ and broadly speaking two distinct hurdy-gurdy types may be chronicled as follows.

*Before the thirteenth century*
The earliest hurdy-gurdies were large two-man instruments, one person being needed to crank the handle and the other to operate the keyboard. This division of labour was necessary not only through the size of the instrument but because of the key action. The 'keys' are best described as revolving bridges each requiring a small twisting movement to bring them into contact with the strings. The action might be compared to turning a series of front-door keys: the player clearly needed both hands for the job and even so speed must have been very restricted. Because of the key cover which protects the mechanical 'keyboard', details are hard to make out in medieval illustrations of the hurdy-gurdy. One source however[18] clearly shows that the bridges press against all three strings. Although details of tuning are uncertain, this does suggest some kind of 'mixture' arrangement. If the tuning was in fifths and octaves, for instance, the hurdy-gurdy would have played in a kind of strict parallel organum and some of the names given to the instrument – *organistrum, symphonia,* and *armonie* – do suggest an association with early polyphony.

*After the thirteenth century*
Like the organ, the hurdy-gurdy developed a more compact form during the thirteenth century and much improved its key mechanism. Two players became superfluous since the same person could manage both handle and keyboard. The revolving bridges were replaced by keys operating sliding tangents (Latin *tangere*, to touch) which had to be pressed up against the string and then allowed to fall back into position. The keyboard resembled that of the portative organ and the finger action required was similar except that each key had to be pressed upwards instead of downwards. The tangents were arranged so as to be selective: they touched only the melody string, leaving the others to sound a permanent drone. Thus the whole character of the hurdy-gurdy changed: from a slow-moving instrument capable of playing in consecutive fourths, fifths, or octaves it became an ideal instrument for dance music with an agile keyboard for the melody and a fixed drone for the accompaniment. To start with three strings seem to have been the norm: a tuning of G and d for the drone strings and c for the melody strings would correspond with one of the regular tunings of the fiddle. More strings were added and by the fourteenth century there were as many as five or six. The keyboard increased in range too: from a simple diatonic octave it gradually progressed to a fully chromatic two octaves. Mersenne mentions as many as forty-nine keys.[19] It is worth mentioning that the typical waisted or figure-of-8 shape of the hurdy-gurdy, linking it with the fiddle, is found in all periods. The oblong box shape sometimes found illustrated does not represent the prototype, only a variation on the basic form. The hurdy-gurdy continued to flourish during later ages, and it still survives, in countries such as France and Belgium, as a folk instrument.[20]

**Monochord and clavichord**
The principle of the early hurdy-gurdy – stopping a string by means of a series of movable bridges – is related to that of the *monochord*. And for the origins of this instrument we must once again turn to Ancient Greece. First described by the mathematician Euclid in about 300 BC, the monochord dates from the time of Pythagoras three hundred years earlier. According to Aristides Quintilianus: 'as he prepared to leave this earthly life Pythagoras besought his disciples to play the monochord.'[21] Be that as it may, the Greeks developed the monochord as a piece of laboratory apparatus for defining and demonstrating the basic laws of harmonics and teaching scales and intervals. It consists of a simple oblong sound box equipped with two bridges and a string stretched over them, hence the name monochord (*monos* meaning one, *chordè* meaning string). The string is attached at one end and held in position by a weight or peg at the other. Besides the fixed bridges there is a movable bridge used to

divide the string at different points. The monochord was eagerly adopted by the medieval theorists. According to an anonymous scholar of the tenth century: 'Just as the teacher first shows the letters in a table, so the music teacher can show all the notes of the chart with the help of the monochord.'[22] Using some kind of plectrum to sound the string, the teacher would have begun his lesson by demonstrating the simplest ratios between two sections of vibrating string. If the bridge was placed so as to divide the string in the ratio 1:2 the interval was an octave (*diapason*); if the ratio was 2:3 the interval was a fifth (*diapente*); if the ratio was 3:4 the interval was a fourth (*diatessaron*); and so on.

In spite of its name, the monochord seems to have acquired more than one string, probably to demonstrate the effect of sounding several notes at once.[23] But whilst the Greeks restricted its use to a piece of scientific equipment, at some point during the Middle Ages the monochord became a musical instrument in its own right. As a *monacorde*, or the corrupted *manichord* or *manicordio*, it is mentioned in French romances and courtly epics and depicted in miniatures from the time of the troubadours. Whilst this aspect of the monochord's career was fairly short-lived, as a measuring apparatus it continued in use right up to the nineteenth century and is mentioned by such authorities as Zarlino (1588), Kircher (1650), Mattheson (1739), and Paul (1868).[24]

As it stood at the end of the Middle Ages the monochord was of greater potential than practical use. Having to move the bridges to obtain different notes exercised the same sort of restraint as having to turn the keys on the early hurdy-gurdy. The solution lay once again in the application of the keyboard principle, though unfortunately we do not know the precise date or whereabouts of the clavichord's invention. As Sebastian Virdung says in his *Musica getutscht* (1511): 'But who it was that may have invented it or thought it out, that made a key for every point according to the same division of the string, that strikes the string exactly at that position or point, and then produces that sound only and no other than seems to have been given it by nature at that point of division, that I cannot tell; nor do I know who dubbed or named the instrument clavichord, after those same keys.'[25]

The trouble is that to start with the instrument was not always dubbed *clavichord* but sometimes *clarichord* or *manichord*, a name which stuck throughout the renaissance and baroque periods and causes confusion between clavichord and monochord. To make matters worse, there are a number of fourteenth-century references to an instrument called the *eschiquier, exaquier, chekker,* and other variants. Edward III gave one to John of France in 1360, Machaut refers to the *eschaquier d'Engleterre* in his poem *La Prise d'Alexandrie* (*c.*1367), and King John of Aragon mentions an *exaquier* several times in letters written between 1387 and 1388, on one occasion describing it as *sturment semblant dorguens que sona ab cordes* (an instrument resembling the organ but sounded by strings).[26] Various theories have been put forward as to the indentity of this mysterious instrument, ranging from the clavicytherium or upright harpsichord to a hypothetical instrument which has disappeared altogether. Thanks to the researches of Edwin Ripin[26] it now seems certain that the *chekker* was in fact a clavichord, and we can safely assign the development of the clavichord to the mid-fourteenth century, though there must in all probability have been a period of experiment with different kinds of keyed monochord first.

The clavichord's name is self-explanatory, the application of a key (Latin *clavis*) to the string, but, perhaps less obvious is what the new instrument inherited from the old. Like the monochord, the early clavichord used the same string to produce several notes (two, three, or even four) by stopping the string at different points along its length. Instead of one movable bridge for each string, there was now a bridge for each note, brought into contact with the string by pressing a key on the keyboard. And instead of having a separate plectrum to sound the string, the bridge did that job too, producing a very soft attack. You could compare the sound to that obtained by pressing down a string on the fingerboard of the guitar with the left hand, *ie* without plucking. Because of the process of stopping the string which it shared with the guitar and lute families, the early clavichord became known as *gebunden*, or the 'fretted' clavichord. There were of course, certain notes which you could not play simultaneously because they both employed the same string. On the oldest surviving clavichord[27] there are forty-five keys to twenty-two double sets of strings. But whereas the lowest notes are fret-free, in the upper register several strings have to produce four different notes, for example, f′, f♯′, g′, g♯′. This was rather a restriction if you wanted to play suspensions, although as Praetorius pointed out it certainly saved time in tuning the instrument. Gradually the proportion of strings to keys increased, though throughout the seventeenth century certain adjacent semitones continued to share the same string. It was not until the early eighteenth century that the richer musical vocabulary demanded complete flexibility and some clavichords became fret-free.[28]

From the outset the clavichord must have been an instrument of private practice and recreation. Even though it is sometimes illustrated in consort with other instruments, its soft voice was too small for any kind of competition and is principally designed to delight the ear of the player. It was, and still is, an ideal practice instrument for organists, enabling them to play at home instead of in a cold church. Much organ music sounds well on the clavichord, for instance many of the pieces in the famous Buxheim Organ Book[29] (*c.*1470), which the late Thurston Dart suggested may in fact have been intended for the clavichord.[30] Specific repertory for the clavichord does not occur until the seventeenth century and it was not until the baroque period that makers were encouraged to increase the range and volume beyond the tiny sound of the small fretted clavichord of the Renaissance.

# 3 Brass

The medieval ancestors of the modern trumpet, horn, and trombone were not always made of brass. Many different materials were used for their construction, including other metals, ivory, and horn, so strictly speaking we should call them 'cup mouthpiece' instruments rather than brass instruments. In common with the modern orchestral brass, medieval trumpets and horns were sounded by blowing into a cup-shaped mouthpiece. The player used different lip pressures to obtain different notes: slack pressure for low notes, tighter pressure for high ones. The mouthpiece (often an integral part of the instrument rather than a separate unit) varied considerably in shape and often restricted the player to one or two notes rather than encouraging the development of a wide range.

**The trumpet**

The early trumpets, without slides, valves, or finger-holes, were in any case restricted to the 'natural' notes obtainable from an open tube, that is the notes of the harmonic series. The pitch of the notes is dependent upon the length of the tube, but the intervals between the notes are always the same. An instrument eight feet long produces a fundamental note of approximately C below the bass stave, and a rising series of 'open' notes belonging to the common chord of C.

It seems unlikely that medieval trumpeters ventured much further up the harmonic series than this. Like modern buglers, they must have compensated for any lack of musical variety by the volume and brilliance of their tone. The exact nature of medieval trumpet calls will always remain something of a mystery, since there is virtually no written evidence before the sixteenth century. But the Burgundian composer Guillaume Dufay gives us a fascinating glimpse of what medieval fanfares may have been like in his Gloria *ad modum tubae* written in about the year 1420.[1] As the title *in the manner of a trumpet* suggests, the two instrumental parts of the Gloria consist of fanfares playable on medieval trumpets pitched in C. Only four notes are used in each part: g c′ e′ g′, that is, harmonics 3 to 6 as shown above.

Pictorial evidence confirms that the typical medieval straight trumpet was an imposing instrument over six feet long. It was usually made in jointed metal sections, often with a flared bell, and was commonly known as the *buisine*, a corruption of the latin *buccina*. Shorter trumpets of two or three feet in length were distinguished by the name *claro*, or *clarion*. The word trumpet – a diminutive of *trump* or *trompe* – seems to have been used rather indiscriminately to cover many different types. The claro was particularly suited to military use. It was easier to carry about than the more cumbersome buisine, and its high-pitched signals could be clearly heard even in the heat of battle. In *La Prise d'Alexandre*, Machaut mentions all three names: 'Trompes, buzines et trompettes' and elsewhere he distinguishes between the *Trompe* and the *Trompe petite*.[2]

The long trumpets were ideal for ceremonial music: a dozen or more buisine players with standards flying from their instruments made a splendid impression on the eye as well as the ear, a fact which kings and princes were quick to appreciate. Trumpets became the prerogative of the nobility; trumpeters together with their attendant drummers were an essential part of every royal household. They acted as heralds on all public occasions, travelled in the royal retinue, and occupied a more elevated social position than most other professional musicians. As early as 1087, at the siege of Rochester, William II took possession of the town with a royal blaze of trumpets,[2] and the instrument's popularity was subsequently encouraged by the Crusades. The pomp and splendour of the Saracen bands of shawms, trumpets, and drums impressed the crusaders and encouraged them to form similar bands of their own. An alternative French name for the buisine was *cor sarrazinois* (*Saracen* horn).

There are various survivals of the medieval trumpet. The post horn retained the clarion's function as a signalling instrument right up to the end of the nineteenth century. The traditional birchbark trumpet, still made and used by Swedish shepherds, offers a living example of the clear ringing tones which the buisine must surely have had. The Moroccan trumpet still retains its old ceremonial associations and a place in the outdoor band along with shawms and drums. In Marrakesh such a band can still be heard playing for wedding processions, with the trumpets supplying a continuous low drone. The Moroccan trumpeter is very much a one-note man, quite content with a supporting role in the ensemble. It is likely that this sort of performance practice spread to Europe from the East during the Middle Ages, particularly for dance music.

**Cow horn and oliphant**

In one sense the medieval trumpet's musical limitations were its virtue: it was isolated from all other instruments. But as far back as late Saxon times men had already begun to look for some way of filling in the gaps between the natural notes of the harmonic series. The whole history of early brass instruments consists of the the different attempts which were made to cope with this problem. The first attempt combined techniques of brass and woodwind. Cow and goat horns had already been used as signalling instruments for many centuries. With the tip removed to enable a mouthpiece to be carved into the narrow end of the instrument, a couple of useful and fairly booming notes could be produced, a fourth or fifth apart. By the tenth century finger-holes were added, making possible a series of consecutive notes so that the horn could be used for simple melodies. Cow horns with three finger-holes are still made by Scandinavian shepherds: by skilful use of a

couple of hand-stopped notes they can produce a useful range of a sixth. Because the bore of the horn is conical, as opposed to the trumpet's basically cylindrical bore plus bell, the tone is plaintive rather than aggressive.

Long after the development of the finger-hole horn, hole-less instruments continued to be used. The most splendid variety was the *oliphant* (from the French *cor d'olifant*, elephant's horn). These ivory instruments reached the West from Byzantium during the Middle Ages and were highly prized. Although their musical use was as restricted as the simplest cow horns they were often richly carved and became the symbol of royalty.[4] The oliphant crops up regularly in medieval French literature and the instrument continued to be made throughout the Renaissance and into the seventeenth century. In the treasury of St Guy's Cathedral, Prague, is the famous hunting horn thought to have been sounded by Roland, nephew of Charlemagne. Legend has it that the sound of this horn carried for an amazing distance. When Roland lay wounded in the Pyrenees in the year 778 he blew the horn to summon help. The story goes that Charlemagne heard him from many miles away, but Roland blew so hard that he burst an artery in his neck and cracked the horn.[5]

**The medieval cornett**

Scandinavia is also the home of another interesting medieval survival, the Finnish *tuohitorvi*. This represents an interim stage between the fairly primitive cow horn and the sophisticated cornett (literally 'little horn') of the renaissance. The finger-hole horn was an extremely limited instrument. There was normally room for no more than three finger-holes, the overall pitch was entirely dependent on the dimensions of the animal horn, and the maker had very little control over the sort of instrument he could make. So at some stage towards the end of the Middle Ages, makers changed from horn to wood. The tuohitorvi provides us with a typical cornett prototype. It is made in two halves hollowed out lengthwise and then glued together and bound with bark. The shallow cup mouthpiece is carved at the narrow end of the conical bore and a piece of horn is inserted at the other by way of a bell, a reminder of the tuohitorvi's animal horn ancestry. There are five finger-holes and thumb-hole, and the instrument speaks well over a diatonic range of an octave and a half, the lowest note being approximately the A below middle C.

The development of the medieval cornett may well have taken place in Germany and Austria. Amongst the instruments listed at the Feast of the Pheasant in Lille in 1454 is a *German* cornett,[6] and a manuscript containing the songs of Hermann, monk of Salzburg (late fourteenth century),[7] provides evidence of interest in wind playing in the Alpine regions. Many of the songs are based on popular Alpine melodies and three are described as *gut zu blasen* (good for blowing). The titles *das nachthorn* (the night-horn), *das taghorn* (the day-horn), and *das kchühorn* (the cow-horn), suggest the use of an instrument of the finger-hole horn or cornett type, and the fairly crude part-writing seems to reflect a popular instrumental rather than vocal style. It is hardly surprising that cow-horns and cornetts developed in mountainous regions where the raw materials were readily available and where their carrying power would be useful. It is in just such regions of Scandinavia and elsewhere that folk survivals are found today.

**The slide trumpet**

A fourth piece by the Monk of Salzburg is entitled *der trumpet*, and if by this Hermann intended the trumpet to participate in the performance he must have meant some kind of *slide* trumpet, since the range of the parts excludes any instrument relying purely on the harmonic series. The date at which the slide trumpet first appeared is uncertain, though it may be as early as the fourteenth century, when the Spanish word *sacabuche* (literally 'draw-pipe') was in use.[8] It developed from the *buisine*, which towards the end of the Middle Ages was lengthened, and to avoid an instrument of inordinate length was re-formed into a flattened S shape. The fact that the tube was cylindrical made possible a telescopic mouthpipe: the player could steady the mouthpiece against the lips with one hand and slide the whole instrument in and out along the mouthpipe with the other. So whilst the cornett had *shortened* the sounding length of the tube with a series of finger-holes, the slide trumpet *lengthened* the sounding length with a series of extended slide positions. The theory behind this invention was brilliant, but in practice the slide trumpet must have proved tricky to handle. Since the mouthpipe is a single tube, not a double one, each slide position is roughly twice as long as that of the modern tenor trombone. This in itself makes fast passages a problem, but the difficulties are increased by the basic imbalance of the instrument. The moving section is so much heavier than the slender mouthpipe that an over-hasty return to first position can knock the player's teeth out.

Other names for the slide trumpet include *draw trumpet*, *Zugtrompete*, and *trompette des ménestrels* (minstrels' trumpet). Modern reconstructions based on surviving illustrations suggest that the slide trumpet would probably have been pitched in C or D with a comfortable range of f to a′ or g to b′. It is several times depicted playing with shawms for the *basse danse*, the most popular court dance of the fifteenth century. The slide trumpet would have been ideal for the slow-moving tenor part on which the dance was always based. A handful of fifteenth-century works appear to have been written with the slide trumpet in mind.[9] They range from Mass sections, such as the Gloria by Arnoldus de Latins with a contratenor marked *Tuba sub fuga*, to the *rondeau J'ayme bien* by Pierre Fontaine with its contratenor *Trompette*, added almost certainly by Guillaume Dufay in 1434 or 1435.[10] As it stands the two-octave range of the latter part (D–d′) lies far too low for any kind of slide trumpet. Yet according to the composer Adam of Fulda a feature of Dufay's compositions was the way he added several notes in the bass register in order to accommodate instruments.[11] One cannot help wondering if this part was designed for an early type of sackbut on which the U-shaped slide could cope with the low notes (see chapter 8, page 68). By the early sixteenth century the slide trumpet had been largely superseded by the sackbut, though the instrument continued to be used in Germany well into the eighteenth

century. The *tromba da tirarsi* required in seven of Bach's cantatas is a slide trumpet, though the English slide trumpet of the baroque period represents a quite different line of development involving a *backward*-operating *double* slide. The *flat trumpets* which Purcell calls for in his funeral music for Queen Mary (1695) are of this latter type.

Because of their antiquity and their diverse and widespread forms, stringed instruments present a complex problem for the historian. Tracing and documenting their development in Europe during the Middle Ages is a far from easy task, made particularly difficult by the stylized representations of medieval art and the ambiguous and confusing way in which names were used by contemporary writers. The word *vielle*, for instance, described instruments as different as the medieval fiddle and the hurdy-gurdy. Before the tenth century *lyra* signified lyre, during the later Middle Ages it was applied to the rebec, harp, or even lute, whilst during the Renaissance it meant *lira da braccio* as well as being used for the hurdy-gurdy and a style of viol playing. The word *chrotta* and its variants (*rotta, crot, rote,* etc.) seem to have been applied at various stages to the harp, lyre, crwth, and hurdy-gurdy. Modern research has not yet managed to sort out all the problems and occasionally has even compounded the confusion. Mistakes have been made over dating, translation, and (especially) the interpretation of iconographical evidence. Tuning keys have been identified as plectra, plectra have been identified as bows, and in the case of a famous drawing in the Utrecht Psalter (AD 860) a long pole has been variously defined as a bow, a sword, and a measuring rod.[1] Because of the restricted scope of this book, what follows will inevitably involve some degree of over-simplification.

## Instruments with open strings only

The harp and lyre represent two of the most ancient types of stringed instrument. Each played an important part in various pre-Christian civilizations and both still survive all over the world in many primitive forms. Relatively sophisticated forms of harp and lyre have been in existence for five thousand years and were amongst the most valued instruments in the Babylonian and Egyptian civilizations. Although obviously different in construction, shape, and playing technique, they are linked with the psaltery and dulcimer by their exclusive use of open strings. Because none of the strings is stopped with the fingers, as on the violin or guitar, each string will produce only one note, and the range of the instrument is therefore entirely dependent on the number of strings.

In the Middle Ages strings were made principally from twisted animal gut (usually sheep gut), though horse hair and even silk were occasionally used.[2] From the thirteenth century onwards metal came increasingly into use, and wire strings were made of copper, steel, and even silver. Metal was found particularly serviceable on instruments which were struck, such as the dulcimer, or plucked with a plectrum, such as the psaltery. The tone was louder and more brilliant and the strings themselves were less liable to break. Harps too were strung with metal as well as gut, in spite of normally being plucked with the fingers or finger nails.

The instruments in this section are also linked by their method of tuning. Each string was attached to a wooden peg or metal pin and the string tension was normally adjusted with a tuning key. The system of tuning was diatonic, never chromatic, and restricted the instrument to one mode or basic scale at a time. Thus an instrument tuned in the Dorian mode would only be able to play the following notes:

Yet a piece written in the Dorian mode was quite likely to demand an occasional B♭ or C♯, and just how the players coped with such accidentals is rather a puzzle. There seems to be no evidence for any quick-change device like the little metal flaps fitted on the modern Arab *qānūn* which enable the players to alter the pitch of a course of strings with an adroit flick of the fingers. Equally the levers found on the traditional Irish harp placed below the tuning pins to raise the pitch of each string by a semitone are a fairly recent development. Just what medieval players did do to obtain

accidentals remains unclear. Perhaps they had their own rules of *musica ficta* by which they altered the difficult notes or even left some of them out altogether. A surprising number of medieval illustrations do show tuning keys ready to hand, particularly with harps and psalteries. So it may be that certain notes were re-tuned during performance, even though this involved playing with one hand only.

**The harp**

The question of accidentals is especially perplexing with regard to the harp, whose high standing and importance in medieval music-making are unquestioned. According to the twelfth-century *Laws of Wales* the three things indispensable to a gentleman were 'his harp, his cloak, and his chessboard' whilst the three proper things for any man to have in his house were 'a virtuous wife, his cushion on his chair, and his harp in tune'.[3] According to Guillaume de Machaut the harp was the best of all the soft instruments[4] and the survival of 'Harper' as a common English surname is an indication of the popularity of the instrument. If only medieval harpers had developed their own system of notation,[5] as organists and lutenists did, we should be a great deal wiser about exactly how the harp was used. It would be fascinating to know just how it accompanied the monophonic songs of the troubadours, or what the free preludes were like which apparently prefaced singing and recitation on formal occasions. The harp must have developed quite an extensive solo repertory during the Middle Ages, including some kinds of part music, but performers must have relied primarily upon memory and improvisation.[6]

There can be no doubt that the harp was customarily played with great expressiveness and brilliance. The latter effect was sometimes obtained by plucking with the fingernails rather than the tips of the fingers. There are several references like that which occurs in the thirteenth-century *Kyng Horn*: 'Teach him to harpe with his nayles scharpe.'[7] In 1183 Giraldus de Barri, court chaplain to Henry II, commented on the technical facility of the Irish harpers: 'Their style is not, as on the British instruments to which we are accustomed, deliberate and solemn but quick and lively . . . It is remarkable that, with such rapid fingerwork, the musical rhythm is maintained and that, by unfailingly disciplined art, the integrity of the tune is fully preserved throughout the ornate rhythms and the profusely intricate polyphony . . . They introduce and leave rhythmic motifs so subtly, they play the tinkling sounds on the thinner strings above the sustained sound of the thicker string so freely, they take such secret delight and caress [the strings] so sensuously, that the greatest part of their art seems to lie in veiling it . . .'[8]

Such technical facility is certainly the hallmark of South American players today, who still use the lineal descendant of the sixteenth-century Spanish harp. Their astonishing agility in repeated broken-chord patterns or scales of consecutive thirds or octaves is a reminder that the diatonic harp can be a virtuoso's instrument and their sharp aggressive attack is a far cry from the delicate rippling effect we associate with the orchestral harp today. During the Middle Ages harpers must have displayed a mastery of different playing styles but there certainly seems to have been a penchant for hard rather than gentle tone. For instance, a 'buzzing' or 'rattling' effect could be produced by setting the 'bray' pins so that the strings rattled against them. This practice, particularly effective on wire-strung harps, is mentioned as late as 1619 by Praetorius: 'On the [common] harp . . . the strings also rattle and crackle if they come into contact with the pegs with which they are fastened into the frame of the instrument, at the bottom. This rattling is usually referred to as *harfenierend* or a harp-like sound.'[9] (See harp with 'bray' pins on p. 74.)

The principal feature which distinguishes the harp of medieval Europe from its predecessors in the ancient civilizations of the East is its three-sectional construction. Whereas the ancient harp had relied on a soundbox and a peg arm only to support the strings, the addition of a fore pillar completed the triangular frame and produced a firm sturdy structure. Tradition gives Ireland the credit for this development, but although the frame harp certainly flourished in Celtic lands its origins remain obscure. It is regularly illustrated from the ninth century onwards and shapes and sizes seem to have varied enormously.[10] Some illustrations show as few as six or seven strings, but the twelfth-century troubadour Guiraut de Calanson recommends seventeen strings and in the fourteenth century Guillaume de Machaut compares the twenty-five virtues of his lady to the twenty-five strings of his harp.[11] The harp acquired an equal variety of names. The word harp itself probably derives from an Indo-European root meaning 'to pluck'. Regional names included the Irish *cruit*, the Scottish *clarsach*, and the Welsh *telyn*, whilst the medieval theorists used *lyra, harpa, chrotta,* and *cythara*. As late as 1511 Sebastian Virdung complained: 'What one man calls a harp, another calls a lyre.'[12]

The harp played an important part in legend and folklore. Not only was it traditionally King David's instrument but popular superstition credited the harp with supernatural powers which could 'destroy the feynde's myght'.[13] In the tenth century St Dunstan, Archbishop of Canterbury, was charged with sorcery because he left his harp where the wind could blow through the strings, producing magical and mysterious music.[14] Other stories include that of Alfred the Great who entered the Danish camp disguised as a harper (*c.* AD 878) and the famous Irish legend of the curse of St Ruadhan (AD 560) immortalized in the ballad 'The Harp that once through Tara's Halls'.[15] At this early date, however, it is more likely to have been a lyre, rather than a harp, which remained mute for evermore.

**The lyre**

Europe inherited the lyre from classical antiquity and preserved its function as an accompanying instrument. Anglo-Saxon minstrels used the lyre for support during the recitation of a great epic or romance, though musically the support must have been of a very simple kind, whether melodic or chordal. The typical early medieval lyre had six or seven strings running from the tuning pegs over a bridge to a tailpiece fastened at the base. Unlike the classical yoke-plus-neck design the instrument was of solid construction, with a slightly waisted shape. The body was

hollowed out for some distance into the arms and the exposed area covered with a sound-board.[16]

From Greek times onwards the lyre occupied a place in mythology as well as real life, and this gives rise to accounts of miraculous skill in performance. Galpin cites an old Gaelic legend in which a Druid chieftain invokes his magic *crot* (meaning lyre) during a battle which supposedly took place in the year 1800 BC.

'The effect of the Druid's performance was truly wonderful: the story tells how, in order to discover the fate of a favourite musician, he and two comrades had penetrated into the camp of the enemy, where they found the lyre hanging in the banqueting hall. At the voice of the Druid it leaped from the wall and came to him at once, killing nine persons on its way. On it he played the three great musical strains of his nation: at the sound of the first tears filled

all eyes; with the second he overcame them with uncontrollable laughter; and finally, with the third, he sent the entire host to sleep, during which the three champions made good their escape with the magic Crot.'[17]

During the later Middle Ages the lyre was superseded by two instruments of greater musical capability: the harp and the *crowd*, or bowed lyre. During the Renaissance the development of the cittern was a conscious attempt to revive the *kithara*, the lyre of classical times. Yet because of its classical associations and its symbolical significance, the lyre continued to be illustrated long after it had fallen out of practical use.

**Psaltery and dulcimer**

These two instruments may conveniently be dealt with together since they represent different facets of the same basic instrumental type, one plucked, the other struck. Both consist of a sound box above which the strings run from side to side over one or two sets of bridges. The tuning pins are often set on alternate sides and both instruments eventually adopted the idea of courses rather than single strings. A course of two or more strings to each note has several advantages. Besides producing better tone and carrying power, it provides some insurance against breaking strings and, particularly on the dulcimer, gives the player more to aim at than a single thin strand.

The psaltery developed in the Near East and filtered into Europe during the Crusades. It is regularly illustrated from the twelfth century onwards and chiefly goes by two names of Greek origin: psaltery (from *psalterion*) and *canon* or *canale* (from *kanon*). The Arabic *qānūn* today is a large psaltery played with great virtuosity in Middle Eastern orchestras, and is a direct descendant of the forerunner of the European psaltery. Other important survivals are the Finnish *kantele*, and the zither of the Austrian Tyrol.[18] The shape varied enormously: triangular, trapezoidal, square, oblong, even semicircular instruments are illustrated. The most characteristic form was trapezoidal but with incurved sides, and it is clearly this snout-like shape which inspired the Italian name mentioned by Praetorius in 1619, *istrumento di porco* (pig's instrument). The psaltery was played either resting on the lap or leaning up against the chest, and fingers as well as quill plectra seem to have been used. There are many literary references to the psaltery, often listing it in mixed ensembles of various kinds, but evidently it was also satisfactory as a solo instrument. In Chaucer's *Canterbury Tales* the scholar Nicholas diverts himself with the 'gay sautrie' and the romance of *Eger and Grime* provides us with a charming account of a lady psaltery player:

the Ladye lovesome of hew and hyde
sett her downe by his bed side,
shee layd a sowter upon her knee,
and theron shee playd full love somlye.[19]

The dulcimer is basically a psaltery struck with hammers and its arrival in Europe can be chronicled only with difficulty. Since there is very little structural difference between the two instruments, identification in pictorial representations depends on being able to distinguish between plectra and hammers, not always an easy matter. Some authorities have identified dulcimers as early as the twelfth century, others not until the fourteenth. The word dulcimer (*dowsemere, dulcoemel,* etc, later *dulce melos*) first occurs in the fourteenth century and implies that the instrument was endowed with sweetness of tone. The striking action gave rise to the name *tympanon*, variants of which occur in Celtic, French, and Italian. The German name *Hackbrett*, meaning a butcher's board for chopping meat, may have been suggested by the action and the shape of the instrument. Dulcimers were normally trapezoidal and played resting on the lap or on a table. Itinerant musicians of later ages regularly fastened the instrument round their neck with a sling.

Praetorius actually describes the psaltery as a *Hackbrett* played with the fingers, whereas the Italians called the dulcimer *salterio tedesco* – German psaltery. Such evidence confirms the close link between the two instruments, and it is quite likely that during the Middle Ages long plectra were used both to pluck and to strike the same instrument. In the East the psaltery and dulcimer had evolved their separate identities before their introduction to Europe. The home of the dulcimer seems to have been Persia, where as the *santur* (derived from the Greek *psalterion*) it is still played with great brilliance today. Survivals of its migration westward include the Greek *santouri* and especially the Hungarian *cimbalom*, a large concert instrument which has occasionally found its way into the modern orchestra (as in Kodály's suite *Háry János*).[20] The dulcimer spread eastwards too. As late as 1800 it reached China where it is still referred to as *yang ch'in*, the *foreign* zither.

Although the tuning of both psaltery and dulcimer was invariably diatonic during the Middle Ages, the compass and number of strings varied enormously. Large instruments are illustrated, with sufficient string length for quite deep bass notes. In 1528, Agricola describes a psaltery with a compass of over three octaves descending to F. Even if this was unusually low, some medieval dulcimers and psalteries would have been large enough to cope with tenor and contratenor parts in chansons, *musica ficta* permitting. But judging from surviving folk music practice, the chief glory of the dulcimer and psaltery was their treble register, from about middle C upwards. This would have made them ideal for solo dance music or for decorated versions of chanson treble parts.

Both instruments were ultimately superseded by the development of the keyboard: the psaltery by the virginals and harpsichord with their 'plucked' action, the dulcimer by the piano with its mechanical hammers. After the fifteenth century, the psaltery fell out of regular use, though the dulcimer continued to flourish in the realm of popular music. On 14 May 1662 Samuel Pepys heard one in the band playing for the puppet play at Covent Garden. 'Here, among the fiddles, I first saw a dulcimer played on with sticks, knocking of the strings, and is very pretty.'[21] In the early eighteenth century the German Pantaleon Hebenstreit became an international touring virtuoso on the dulcimer. In 1717 Gottlieb Schröter, one of the 'inventors' of the piano, claimed that Hebenstreit's playing had given him the idea for the piano's hammer mechanism.[22] It is curious to reflect that the essential details of piano mechanism were worked out as early as the middle of the fifteenth century. A manuscript compiled by Henri Arnault of Zwolle, physician to the Duke of Burgundy, describes a special type of *dulce melos* in which the strings are hit by a rebounding tangent which is jerked upwards by a checked key.[23] A *dulcemel para tañer* (=keyboard type of dulce melos) is also listed in an inventory of 1503 as belonging to Queen Isabella of Spain.[23]

## The fretted instruments

Whilst the plucked instruments so far discussed all emerged as fairly distinct types during the Middle Ages, it is rather harder to sort out those which involved stopping the strings against a fingerboard, marked off by means of a series of frets. The principle of the lute and its relatives is a very ancient one. The earliest 'lute-like' instruments appear in Mesopotamia in about 2000 BC:[24] they had small bodies, long necks with many frets, and two strings which were played with a plectrum. Since then the lute has occupied a place of honour in many different civilizations ranging from Islam to China,[25] though nowhere outside Europe has it developed such a bewildering number of relatives, all employing a similar plucking action and fretted fingerboard. Bearing in mind the inconsistency of much medieval evidence, iconographical and literary, it may be as well to start by establishing what are important differences of construction and what are just variable details. The fundamental distinctions would seem to be based on the following points:

1. Strings: whether they are made of metal or gut.
2. Frets: whether they are made of gut tied round the fingerboard and therefore easily movable or glued-on pieces of wood or metal and therefore fixed.
3. Bridge: whether or not the strings pass over a movable bridge.
4. Back: whether the back of the instrument is flat (as on the guitar) or rounded (as on the lute).
5. Shape: whether the body is waisted (as on the guitar) or pear-shaped (as on the lute and cittern).

Of course, individual instruments display other important characteristics, but these points help to distinguish the three lines of development which in the Renaissance produced three individual types of plucked, fretted instruments. In order to help distinguish their ancestry they are summarized here.

a. *The lute,* with gut strings, gut frets, no movable bridge, a round back, and a pear-shaped body.
b. *The guitar,* with gut strings, gut frets, no movable bridge, a flat back, and a waisted body.
c. *The cittern,* with metal strings, fixed frets, a movable bridge, a flat back, and a pear-shaped body.

During the sixteenth century these three types all possessed their own idiomatic systems of tuning. Unfortunately next to nothing is known about the tuning of their medieval ancestors. Some authorities, notably Curt Sachs,[26] have attached great importance to the position of the pegs (frontal, rear, or lateral) in distinguishing types of stringed instrument, bowed as well as plucked. Yet although the nature of the peg box was important, especially with the distinctive shape which developed on the mandora, there seems to have been such a variety of forms in the Middle Ages (just as in folk instruments today) that it is not until the more standardized types of the Renaissance that the details of the peg box regularly conform with other details of construction. Much the same can be said about the shape and placing of the sound-holes.

From the five distinguishing points listed above, it is obvious that iconographical sources

will be no help for 1 and 2: you cannot *see* whether strings are metal or gut or whether frets are fixed or movable, and if the right hand is in a playing position you can often not be sure of the existence of a movable bridge either. So we are obliged to rely on literary evidence, which from the Middle Ages is very scanty. There is one point, however, which is beyond dispute and which links all the instruments in this section: their playing technique. The strings were plucked not by the fingers but with a plectrum, and although lutes and guitars seem so obviously *chordal* to us, their medieval ancestors were used primarily as *melody* instruments. The plectrum – usually a long quill – produces a hard attack and bright tone, ideal for a clearly etched single line. But its use inevitably restricts the possibilities of chord or part playing: it is rather like playing the piano with one finger. You can aim for one string at a time or use a strumming action to sound all the strings at once, but what you cannot do, if readers will pardon the pun, is to pick and choose. If, for example, you want to play a chord involving top and bottom strings but missing out the rest, you have to abandon the plectrum and pluck with your fingers instead, which is exactly what lutenists did during the course of the later fifteenth century.

**The lute**

The lute and its playing technique filtered through to Europe from the East, as a result of the Moorish occupation of Spain and the Crusades. We borrowed the Arab name *al 'ūd* for our words *lute, luth* (French), *Laute* (German), and *lauto* (Italian). In the Middle East today you can still buy the most exquisitely made lutes, particularly in Damascus which is regarded as the Mecca of lute making. The old playing traditions survive too, giving us a good idea of what the monophonic style of the Middle Ages was like. Listening to Arab players today makes one realize that there is almost as much difference between the sound of the lute that Machaut knew and that of Dowland's time as between the psaltery and the harpsichord or the dulcimer and the piano. And the repertory was equally distinct too: the medieval lute was primarily an ensemble instrument, not a solo one. In polyphonic music it would have played a single line, perhaps doubling a sustained part and adding, impromptu, some of its own idiomatic embroidery.[27] Here is Tinctoris writing in about 1487 and giving us the clearest description we have of the medieval style of lute playing:

'The lyre which is called the lute, we use at feasts, dances and public and private entertainments, and in this, many Germans are exceedingly renowned. Thus some teams will take the treble of any piece you care to give them and improvise marvellously upon it with such taste that the performance cannot be rivalled. Among such, Pietro Bono (Avogari) lutenist to Ercole, Duke of Ferrara, is in my opinion pre-eminent.'[28]

The lute first appears in Europe during the second half of the thirteenth century, though at first the evidence is scanty. The *Roman de la Rose* (*c.*1260) and other French sources of the thirteenth century use the name *leu*.[29] In the following century the lute crops up more often. Machaut, Chaucer, and Boccaccio all mention it and artists start to illustrate it regularly.[30] The typical features are the rounded back, short fretted neck, and bent-back peg box with lateral pegs. As surviving specimens show,[31] the earliest lutes were carved out of the solid: the construction employing a series of separate ribs was a development of the Renaissance. There are four strings, attached to a fixed bridge on the sound-board, and the earliest tuning employed is thought to have been a series of fourths, adopted from the *'ūd* and still used by Arab players today. During the fifteenth century one of the fourths became a third, giving a tuning of c, f, a, d′ to which a top g′ string was added (the pitches were relative rather than absolute). Details of the plectrum are forthcoming from many pictorial sources. The long stem of the quill is shown held between the third and index finger (as a modern guitarist holds a flat pick) or between index or middle finger, or even between the two middle fingers.[32] The number of frets seems to have varied considerably: some pictures show as few as four whilst the design of Henri Arnault, one-time court physician and astrologer to the Burgundian court, shows a dozen frets.[33] However, the typical fifteenth-century lute had no more than eight frets.

**The mandora**

Before the appearance of the standard lute, there is plenty of evidence for the existence of a smaller, more compact version called the *mandora* (from the Greek *pandoura*). Illustrations of it have been tentatively identified as early as the ninth and tenth centuries[34] and it is mentioned in early Provençal poems such as *Flamenca*:

L'us mandura e l'autre acorda
Lo sauteri ab manicorda.
(The one [plays] the mandora and the other tunes the psaltery to the monochord.)[34]

From the twelfth to the fourteenth century, the instrument is regularly referred to in French literature as *mandoire* or sometimes *mandola* and illustrations often reveal the instrument's most recognizable feature: its sickle-shaped pegbox. This is not universally shown, however, and the chief characteristic of the mandora was its small size: several literary references to the standard lute show that by contrast it was regarded as a *big* instrument.[35] The mandora's initial popularity seems to have been in Spain, Italy, and Southern France and it gradually worked its way north in Europe, reaching England probably at the end of the fourteenth century.[36] Because of its Greek root *pandoura*, the mandora has sometimes been confused with the *tanbura* and thought to have been a type of long-necked lute. There seems every reason to believe otherwise, however. Praetorius[37] gives the tuning g d′ g′ d″ for the instrument which may well reflect medieval practice too. Such tuning in fourths and fifths is likely to have been used on the rebec with which the mandora was interchangeable,[38] the two instruments representing bowed and plucked versions of the same type.

**The long-necked lute**

The phrase 'short-necked' has already been used to describe the standard type of lute and it serves to distinguish it from the long-necked

lute. This instrument, similar in basic design to the Mesopotamian depictions of the lute from 2000 BC, is illustrated in Europe as early as the ninth century[39] and survives in many parts of eastern Europe and the Middle East today. Instruments such as the Bulgarian *tanbura*, the Turkish *buzuk*, and the Persian *tàr* share a similar appearance and construction: a finger-board two or three times as long as the sound-board, a large number of gut frets, a small oval body and rounded back, and four strings attached to a tailpiece and passing over a movable bridge. The use of a bridge creates as important a distinction from the standard lute as does the long neck. Although such survivals help us to determine what the long-necked lute sounded like, we are not quite sure how widespread its use may have been. The main problem is matching up the instrument with a contemporary name. In Juan de Ruiz's *El Libro de Buen Amor* (*c.*1350) we read:

Ally sale gritando la guitara morisca,
Delas boses aguda e delos puntos arisca.

(There comes out, shouting, the *guitarra morisca* with its sharp sounds and shrill notes.)[40]

This sounds very like the tanbura or buzuk of today: their metal strings do produce a harsh brilliance, quite different from the normal lute, which Ruiz goes on to mention under the name *el corpudo laúd* – the bellied lute. Another Spanish source, the thirteenth-century *Cantigas de Santa María*,[41] includes illustrations of both short- and long-necked types. It seems quite likely that if the Arabic long-necked lute came into Europe through Spain it could have retained in its name some kind of Moorish association, and if this were the case it would help to clear up a number of puzzling references. In 1349 a list of musicians employed by the Duke of Normandy includes players of the *guiterre latine* and the *guiterre moreche;* Machaut twice uses the word *morache* coupled with lute; and as early as *c.*1300 Johannes de Grocheo mentions a *quitarra sarracenica*.[42] Unfortunately we cannot be sure that any of these names refers to the long-necked lute, though Curt Sachs and other scholars have thought it quite likely.[43] It is possible, however, that the names refer to an instrument of the mandora type (see Lawrence Wright's theory,[49] mentioned below). Ideally one would like to find a name which avoids using the words 'guitar' or 'lute' since the instrument has its own distinctive features belonging to neither type. After the fourteenth century it seems to have dropped out of use in Europe. Tinctoris (*c.*1487) dismisses it (using the name *tanbura*) as a 'miserable and puny instrument which the Turks with their even more miserable and puny ingenuity have evolved from the lyra'.[44] He does, however, mention that the *tanbura* has three strings tuned to an 'octave, fifth, and fourth'.[44]

**The gittern**

Although it has a number of distinctive features of its own, the gittern may loosely be regarded as the medieval ancestor of the guitar. Unlike any of the instruments so far described in this section, it displays the flat back and waisted shape of its descendant. The movable bridge and tailpiece shown on many gitterns distinguish it from the later guitar and link it with the medieval fiddle. Gittern and fiddle are often depicted together and they may to some extent be regarded as parallel developments of the same basic instrumental type: one with a plucking technique, the other with a bowing technique. The fact that frets are sometimes lacking on the gittern confirms this.[45]

A variety of names were used for the gittern; in French *kitaire, ghisterne, quinterne*, as well as *guiterne;*[46] in English *geterne, gyttern,* or even *gythorn*.[47] Although the gittern is mentioned from the early thirteenth century, its heyday seems to have been the fourteenth century. During this period it is depicted in quite a number of carvings and manuscripts and referred to by poets such as Langland, Chaucer, and Lydgate.[45] The gittern sometimes provides accompaniment to the voice, *eg* Absalon in Chaucer's *Miller's Tale:*

He singeth in his vois gentil and smal, . . .
Ful wel acordaunt to his giterninge.[48]

We are particularly fortunate that an actual gittern has survived from the Middle Ages. It dates from about 1300–30 and is now in the British Museum. Although it was unfortunately converted into a violin during the sixteenth century, the body and neck of the original remain. We find the curious neck extension (shown on a few English gitterns) which provides a thumbhole for the left hand. There are four strings, though examples with three or five are also illustrated. During the fifteenth century the gittern seems to have been gradually eclipsed in popularity by the lute. Without wishing to confuse the reader unnecessarily, it has to be pointed out that with certain fretted instuments there is a problem of matching up names and illustrations. According to a theory recently advanced by Lawrence Wright,[49] the instrument so far described as a 'gittern' should properly be classed as a type of citole (or cittern ancestor) whilst the *name* 'gittern' should be reserved for what we now call a mandora, as in *guiterre latine, quitarra sarracenica,* etc., mentioned above.

**The citole**

With the citole we continue with less well charted territory. The main problem is still matching up the name with instrument illustrations and detailed information is sparse. Literary references begin in the early thirteenth century:

Et quant je fui sus levez
Si commenz a citoler.
(and when I have got up I begin to play the citole.)[50]

There are several suggestions that the citole was a delicate, even decorous instrument: it was apparently most suitable for young ladies to play, and in *Les Échecs amoureux* (*c.*1370) its tone is described as sweet:

Et citoles meismement
Qui sonnoient molt doucement
(citoles also, which played very sweetly.)[50]

The generally accepted view is that the citole was the ancestor of the Renaissance cittern,[51] resting on the assumption that the word *cetera* or *cetra*, mentioned from the twelfth century onwards, refers to the same instrument as the citole. The first clear description we have comes from Tinctoris in his *De Inventione et Usu Musicae* (*c.*1487). He uses the word *cetula*. 'Yet another derivative of the lyra is the instrument called *cetula* by the Italians, who invented it. It has four brass or steel strings usually tuned, a tone, a fourth and back again a tone, and it is played with a quill. Since the cetula is flat, it is fitted with certain wooden elevations on the neck, arranged proportionately, and known as frets. The strings are pressed against these by the

Citole; sculpture by Benedetto Antelami (late 12th century–early 13th century). (The Baptistery, Parma)

fingers to make a higher or lower note.'[52]

The instrument which Tinctoris describes is unquestionably the ancestor of the renaissance cittern, with fixed frets, a flat back, and a re-entrant tuning for its four metal strings, *ie* with the fourth course tuned higher than the third. This idiosyncratic feature of the renaissance cittern was more widely applied during the Middle Ages. The earliest account of the tuning of any stringed instrument, that of Jerome of Moravia (*c.* 1250), described three fiddle tunings, one of which is re-entrant.[53] A similar practice survives in the Near East where the melody is played on the two outer strings only leaving the middle strings for drones.

Tinctoris also makes the important point that the *cetula* was an Italian invention. The words *cetera, cetra,* etc. are Italian modifications of the Greek *kithara* and this ties in rather nicely with the earliest cittern-like instrument so far identified from the visual arts: a sculpture from the year 1180 in the Baptistery, Parma.[54] Other representations over the next three centuries, often showing the cittern in the hands of angels,[55] demonstrate many of the cittern's characteristics including the 'wings' at the base of the neck derived from the ancient kithara of classical times. Illustrations of the fifteenth century show thick, widely spaced frets which suggest that the fretting was diatonic, not chromatic as on other fretted instruments.[56] It is also clear that the earliest 'citterns' were carved out of the solid like the gittern and early lute types.

Piecing together all the evidence gives us a fairly convincing picture of what the earliest citterns were like. But whether *citole* specifically meant this type of instrument we cannot be absolutely sure.

## The bowed instruments

The origin and development of bowing forms one of the most intriguing chapters in the history of musical instruments. Before the eleventh century there is no trace of bowing in Western Europe; yet a mere hundred years later bowing techniques are amazingly widespread. Considering that the bow itself was the generic type which had given rise to the harp, lyre, and lute in Ancient times, it may seem surprising that it took so long before anyone thought of using the bow as a means of *sounding* the strings. But once tried, the idea caught on like wildfire and revolutionized the making and playing of stringed instruments. At first it was just a question of the application of the bow to existing instruments: the lyre, the lute, and other plucked types. The evolution of *new* types specifically designed to be bowed

Two traditional fiddle types: a three-string *lira* from Turkey and a two-string *rabāb* from Morocco. (Author's collection)

was a much more gradual process, and during the twelfth and thirteenth centuries there was a proliferation of shapes and sizes. In *The Origins of Bowing*[57] Werner Bachmann illustrates no less than twelve quite distinct shapes of early fiddle types, and his exhaustive survey makes clear the problem of systematic classification. To start with there seems to have been no correlation between different names and different types of construction: *rubebe, rebec, giga, lira, fidula,* and *viella* were all applied fairly indiscriminately by medieval writers to the various types of bowed instrument. Any modern attempt at classification involves using names such as 'fiddle' and 'rebec' more precisely than they were used in the Middle Ages. Thanks to the researches of Werner Bachmann and Mary Remnant, however, a vast amount of information about early bowed instruments is now available and readers requiring a more thorough survey than the scope of this book permits are advised to consult their authoritative writings on the subject.[58] Bachmann includes some fascinating details of medieval techniques of construction.

The use of the bow developed initially outside Europe, probably in Central Asia during the ninth century, and spread first through the empires of Islam and Byzantium. The earliest bows may actually have been a development of the plectrum. Many European illustrations show long rod-like plectra which could easily be used as friction sticks by scraping instead of plucking the strings. During the transitional period the same plectrum was probably used to produce different sounds on the same instrument by ringing the changes on striking, plucking, and bowing techniques. From that stage it was an easy step to equipping the 'bow' with horsehair or some other suitable material in order to make the string resonate more effectively.

Behind the early experiments with bowing there seems to have been an underlying desire to find a stringed instrument which could match the human voice. According to the Baghdad scholar Al Farabi, who lived in the tenth century, 'The instruments which most closely approach the human voice are the *rabāb* and the wind instruments.'[59] The bow gave stringed instruments a new sustaining power: unlike the lute or psaltery, bowed instruments could play a continuous melodic line, vying with the voice in flexibility of tone and phrasing. Nevertheless, in the ancient civilizations of Asia, the status of the new bowed instruments seems to have been fairly low: they were regarded as belonging to the common people rather than the court. Al Farabi tells us that 'Owing to its construction the sound of the *rabāb* is not as strong as that of certain other instruments. From this point of view, the *rabāb* is also inferior to most others.'[60]

Inferior or not, by the eleventh century the bow had reached Europe through Byzantium and Arab Spain. It is Spain which provides us with the earliest evidence of bowing in Europe, including the early eleventh-century miniature in a Catalan Bible showing a large three-stringed instrument supported on the knee and played with a bow shaped like the letter P.[61]

### Rebec and fiddle

From the profusion of European fiddle types in the late Middle Ages, there emerged two distinct forms: the slender pear-shaped type which became generally known as the rebec and the waisted figure-of-eight shape which was most commonly called the fiddle: *fidula* or *viola* in Latin, *fythèle* or *vielle* in French. The use of the last name has led to great confusion – partly because the word *vielle* was later exclusively used for hurdy-gurdy and partly because it is so readily mistranslated as *viol*. As a result, several quite eminent histories of music still perpetuate the idea that the viol was a *medieval* instrument, whereas in fact it was a development of the fifteenth century.

Even when the rebec and fiddle had achieved their separate identities, there was still a wide divergence of types. Details of general appearance, bows, pegs, peg boxes, sound-holes, stringing, and playing position varied considerably. Nor did the question of nomenclature become any less vexed. As late as 1530 John Palsgrave's *Lesclarcissement de la Langue Francoyse* provides translations as follows:

| | |
|---|---|
| Croude an instrument | *robecq* |
| Croudar | *ieuevrde [joueur de]rebecq* |
| Fyddell | *rebeq* |
| Fydlar or crouder | *rebecquet* |
| Rebecke an instrument of musyke | *rebec* |
| I fyddell | *Ie ieoue du rebecq* |
| Can you fydell and playe upon a tabouret to? | *Scauez vous iouer du rebecq et sus le tabouryn, aussi[?]*[62] |

As Mary Remnant says, this brings confusion to the point of ridicule. The name rebec and its continental equivalents (French, *rebebe,* later *rebec;* Italian, *ribeca;* Spanish, *rabel*) derived from the Arab *rabāb*. The body with its rounded back was carved out of the solid and had a flat soundboard added. Whilst the number of strings varied from one to five, Jerome of Moravia tells us that the thirteenth-century *rubeba* had two strings tuned in fifths[63] and Virdung (1511) prescribes three strings tuned in fifths, which seems to have been typical in the later period. In 1528 Agricola depicts a whole family of three-stringed rebecs which he calls *kleine Geigen ohne Bünde* (little fiddles without frets).[64]

During the Renaissance there were certainly rebecs of different sizes: the smallest were

sometimes distinguished by names such as *ribecchino* or *rubechette* and there is also a reference to *grosse Rebebn*.[64] The large bass instrument (and probably the tenor also) would have been played gamba-wise, held between the knees. There is evidence that rebecs of various pitches and sizes existed in earlier times too.[65]

During the Middle Ages, however, the most typical rebec was a fairly small instrument of soprano pitch like its plucked relative the mandora. It is shown being played resting on the shoulder, across the chest, or resting on the armpit. Lateral drone strings (*ie* strings to the side of the fingerboard which are not stopped by the fingers) are sometimes found, though they occur much more commonly on the fiddle.[66] Fretted rebecs are shown in a number of illustrations including the *Cantigas de Santa María*,[67] and the presence of frets emphasizes the instrument's close relationship with the mandora. Folk music survivals and modern reconstructions suggest that the rebec had a thin, nasal tone which can be very penetrating particularly when played in a resonant acoustic. It seems to have been especially associated with song and dance: in *The Miller's Tale* Chaucer describes how Absalon played on his rebec, singing a descant the while:

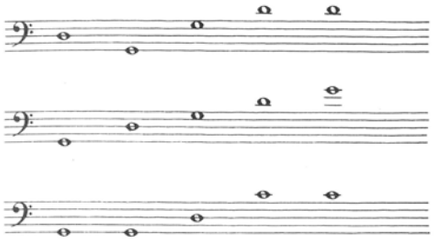
In twenty manere koude he trippe and daunce
After the scole of Oxenforde tho,
And with his legges casten to and fro,
And pleyen songes on a smal rubible;
Therto he song som tyme a loud quynyble.[68]

In spite of its prevalently secular associations Tinctoris selects the rebec, along with the fiddle, as his two 'chosen' instruments. He describes them as 'those that induce piety and stir my heart most ardently to the contemplation of heavenly joys. For these reasons I would rather reserve them solely for sacred music and the secret consolations of the soul than have them sometimes used for profane occasions and public festivities.'[69] Nevertheless it was the royal households who gave rebec players employment, not the Church, and it was as an instrument for dancing that the small rebec survived as the *kit* or *pochette* into the eighteenth century.

In European court society of the Middle Ages the most important bowed instrument was unquestionably the fiddle. 'Further, among all the stringed instruments I have seen, the *viella* deserves to take precedence' writes Johannes de Grocheo, and he also tells us that a good fiddler should be able to 'play anything' since the fiddle 'combines in itself the attributes of all other instruments, and distinguishes most sensitively between all forms of music'.[70] For the privileged classes playing the fiddle was something to be practised not for its usefulness but for its own sake. Whole orchestras of fiddles were maintained at the court of Alfonso 'El Sabio'; fiddlers accompanied their lords on journeys, playing on horseback as they rode; they were also part of the Queen's retinue. In the medieval German epic of Tristan, the Knight spends his days out hunting with the king whilst in the evening he entertains him with songs, accompanying himself on harp and fiddle.[71] Fiddlers were in demand for banquets, weddings, receptions, and celebrations of all kinds. The famous medieval May Song, *Kalenda Maya*, started life as an *estampida* in the repertoire of two jongleurs who played it on their fiddles.[72] The essence of their art was improvisation. In a German account of the *Parsifal* story we read: 'Then Sir Gawain asked if there were no good fiddle players present. There were indeed many worthy fellows and their artistry was so great that they were not constrained to play old dances.'[73] In other words, they made up new ones.

Until the end of the Middle Ages the fiddle was, like the rebec, carved out of one piece of wood with the sound-board added. The back was flat, or nearly so, and the neck was very distinct from the body. The playing position varied, being held on the shoulder, across the body or, in the case of large instruments, between the knees. The existence of this 'gamba' type, most commonly illustrated in the twelfth and thirteenth centuries, has led some authorities to designate it a separate type of fiddle with the name 'medieval viol'. In view of the already existing confusion this is perhaps best avoided. Although the number of strings was variable, as far as tuning is concerned we have some specific information from Jerome of

Moravia, a Dominican monk who lived in Paris *c.*1250. According to his *Tractatus de musica*[74] the three standard tunings for the fiddle were:



Fiddle tunings given by Jerome of Moravia *c.* 1250 (after Bachmann).

These tunings offered the fiddler some variety: he could choose the appropriate one according to the compass and tessitura of the piece he had to play. The idea of doubling the top string, though it may seem rather odd to us, was no doubt a very practical one. The top strings were at the highest tension and therefore were the most liable to break. If one of them did go during a performance at least the doubling gave the player a 'spare' so that he could carry on. Gut strings were clearly thought of as fragile in the Middle Ages and players regularly slackened them off when not in use.[75]

The lowest string was often a lateral drone string: although it was not stopped by the fingers, it could be plucked with the left hand, at any rate when the fiddle was played horizontally, violin fashion. A common method of bowing was to take in several or all the strings at once, and the flat bridges shown on a number of fiddles and rebecs show that instruments were designed for the purpose. A tuning with open fifths and octaves would clearly fit this style best.

One or two final points may be made about both fiddle and rebec. The standard arrangement of bridge and tailpiece was not ubiquitous. Some instruments employed a kind of combined bridge and tailpiece, thus effectively increasing the sounding length of the string in relation to the body.[76] Whilst the ordinary jongleur or ménéstrel was content with a simple unadorned instrument, there are accounts of fabulous instruments marvellously inlaid or bedizened with jewels to bear witness to their owner's wealth.[77] The bow or 'fydylstyk' varied enormously and performers probably made use of several: a short bow for the quick strokes of dance music, a longer one for a sustained part in a chanson.[78] Whilst the 'gamba' position involved underhand bowing, for the 'violin' position of playing an overhand grip was adopted. In general medieval bows seem to have been composed of rather fewer strands of horse hair than modern ones.[79]

Some uncertainty remains over fingering technique. Did players change position or not? According to Jerome of Moravia the answer is no. After describing the notes attainable in the first position on the *rubeba* he wrote 'et non plus rubeba potest ascendere' and proceeded to indicate the same for the *viella*.[80] Alternative tunings certainly facilitated staying in the first position. However, the higher frets shown on some fretted rebecs and fiddles could scarcely be reached without some change of position[80] so it seems possible that players may have used a second or even third position on occasions.

**The bowed lyre**

Bowing techniques were also applied to the European form of the lyre. Out of the delightful selection of names given to it during the Middle Ages – *cruit*, *crot*, *rota*, *rotta*, *chrotta*, *hruozza*, *crwth*, *croud*, *crowd*, *crouthe*, and *chorus* – modern scholars have not quite yet agreed on what to call this instrument. Bachmann (following Sachs) opts for 'bowed lyre'. Remnant (following Galpin) prefers 'crowd'. The name which has remained longest in use, however, is the Welsh 'crwth', used to describe the folk instrument which survived in Wales until quite recent times.

Like the lyre already illustrated (page 23) its bowed successor was made out of one piece, the resonator and pillars of the yoke being hollowed out and the sound board added. Instead of knobbed pegs turned by hand, as on the rebec and fiddle, the crwth regularly adhered to the old lyre tradition of plain pegs which required a tuning key. Some illustrations show the musician in the act of tuning, whilst others show the key attached to the yoke by a thread and dangling down the side of the instrument.[81] To start with players seem to have managed without a central fingerboard in which case the strings had to be stopped either with gentle pressure from the inside of the finger, or else by using the fingernails rather in the manner of hurdy gurdy tangents.[82] Both techniques involve a *sideways* movement of the fingers pulling the string towards the yoke,

rather than *back* towards an imaginary soundboard. To any classically trained string player it sounds horribly inconvenient but similar techniques are still used today on a multitude of bowed instruments without a proper fingerboard such as the Indian *sarangi*, the Arab *rabāb*, and the Yugoslav *gusle*.

A fascinating example of the bowed lyre without fingerboard which just survived into the twentieth century is provided by the *tallharpa* of Swedish Esthonia, whose traditional techniques were chronicled by Otto Andersson.[83] His photographs of veteran players show the instrument almost lying flat across the knees, the bow gripped underhand with the first finger resting on the wood. Andersson says of one player: 'He stopped the strings with his nails or the hardened back of his fingers, which touched the strings obliquely from below, and he did not seem to find this backhanded method of playing in the least awkward . . . The way in which the strings were stopped gave the tone a peculiar quality; it had a soft and gentle effect, somewhat recalling the violin *con sordino*.'[84] Like the typical medieval bowed lyres of the eleventh and twelfth centuries the tallharpa had only three or four strings, of which the lowest consisted of unstopped drone strings. All the strings were sounded at once, a characteristic of bowed lyre technique which is made essential by the instrument's shape: the bow has to remain parallel to the body and cannot be angled as on the rebec or fiddle. Confirmation of the technique comes from the flat bridges shown in medieval illustrations and found on existing examples of both tallharpa and crwth.

The Welsh crwth provides the most developed example of the bowed lyre. It has six strings, a central fingerboard running between the sides of the yoke and its most idiosyncratic feature is the way the bridge also acts as a sound post. Whilst the shorter foot rests on the soundboard the larger one passes through a sound hole and rests on the back of the instrument. A bowed lyre shown on the seal of Roger Wade the Crowder dating from not later than 1316 shows a similar appearance with the later Welsh crwth and may possess this feature too.[85] Although this particular example has only four strings, there is evidence from the twelfth century onwards of five- and six-stringed instruments: some examples with more than ten strings have been noted.[86] Although we have no direct evidence for medieval tunings, the following Welsh tunings quoted in the eighteenth century seem quite plausible: g, g′, c″, c′, d′, d″, and a, a′, e′, e″, b′, b″.[87]

**The tromba marina**

Perhaps the most curious application of bowing techniques was to the monochord. The instrument which resulted – the *tromba marina* (French *trompette marine*; German *Trumscheit*) – was certainly curious and some readers might be inclined to agree with Virdung (1511) who said it was a useless instrument or with Glareanus (1547) who said it made him laugh. A French sculpture of the twelfth century gives us our first glimpse of the tromba marina:[88] the three-sided body is about four feet long and tapers towards the pegbox. There is a single string but at this stage no sign of a bow, suggesting that the instrument was still plucked. By the fifteenth century it had acquired two strings of unequal length and is regularly depicted in action, usually in the hands of angels. A variety of oblique playing positions are shown, varying from resting the larger end of the instrument on the ground to pointing it up in the air. The bowing action however is consistent: the tromba marina plays only natural harmonics and whilst the left hand (usually with the thumb) touches the strings very lightly at nodes near the to the head, the right hand draws the bow across the strings *above* it, near the nut.

Like the monochord, the tromba marina was full of theoretical possibilities and it certainly fascinated the Swiss monk Henricus Glareanus.

Reconstruction of a large bowed lyre of the crwth type by Christopher Wright. The tuning screws on the tail-piece are a modern addition, to facilitate fine tuning.

In his compendious musical treatise the *Dodecachordon* (1547)[89] he devoted a substantial amount of space to the instrument. He tells us how he borrowed a tromba marina and started to experiment in earnest: 'I attacked the problem by myself' he says. The practical details which he includes are most useful and a selection is given here:

'Players go about through the streets with the instrument's point fixed at the breast . . . The instrument produces a more nearly agreeable tone at a distance than it does close at hand . . . They have created the rattling sound by means of a certain curved bridge, whose one wider and thicker foot supports the string at the triangular base, and whose other shortened foot, to which they have affixed a solid substance made of ebony or another hard and shining material, causes this vibrating sound. I had to laugh at this device of men.'[90]

The use of this special type of bridge, balanced on one foot leaving the other free enough to rattle, became the unique feature of the tromba marina, though we are not sure at what stage it was introduced. Various materials were used to 'doctor' the vibrating bridge: Glareanus even mentions driving in a very thin nail which must have produced a devastating effect. A variety of unsatisfactory explanations have been given about the origin of the

instrument's various names.[91] The association with the trumpet is obvious enough through the use of natural harmonics, but the reason for the qualification 'marine' is obscure. Some authorities have derived the word from Mary (*ie* Marian) and one German name for the instrument is *Marientrompete*. In spite of sometimes being called *nun's fiddle* (German *Nonnengeige*) there seems to be no foundation for the theory that the tromba marina was used as a kind of trumpet substitute in convents. Glareanus used the name *tympani schiza*, his Latinization of *Trumscheit*.

In spite of a certain inherent absurdity the tromba marina continued to flourish during the baroque period and even acquired a specific repertory of music.[92] Later instruments (like the gigantic specimen in the Victoria and Albert Museum) were made larger in order to facilitate the playing of the upper harmonics, where the finger positions became very close together. On the small medieval tromba marina it seems unlikely that the player ascended much beyond the eighth or ninth harmonic, and the instrument's use must have been limited to simple fanfares or drones. The unequal string lengths imply a tuning in fourths or fifths.

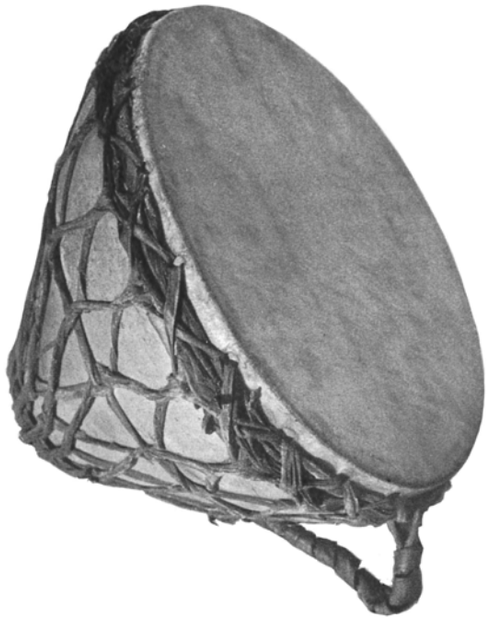
The existence of a wide variety of percussion instruments in the Middle Ages is well documented in both literary and iconographical sources. Folk music has preserved one or two types more or less intact, such as the French *tambourin* and the Spanish castanets, whilst the musical traditions of the East provide us with examples of small cymbals and tambourines with heavy brass jingles. For the rest there is enough evidence of practical details for convincing reconstructions to be made.[1] What is totally lacking is precise information from the Middle Ages or early Renaissance about how percussion instruments were used. They must have been regularly employed for dance music but what other sorts of music did they take part in? In spite of the numerous angels shown holding cymbals, triangles, and tambourines, the regular use of such instruments in church music seems unlikely. When they were used, what sort of techniques were employed? And what sort of rhythms did the drummers use? Did they stick to a basic beat or indulge in wild improvisations like Middle-Eastern players today? This is the most uncharted area of early music performance practice and our answers must consist in the main of inspired – or, as the case may be, uninspired – guesswork.

As Jeremy Montagu has pointed out[2] there are one or two basic guidelines. Pictures provide valuable information about the way sticks and instruments were held: the playing position for cymbals and tambourines, for instance, was quite different from that used by orchestral players today and so the playing styles must have been different too. Jeremy Montagu makes the following important point: 'Before AD 1500, all drum names in European languages had a *ram-* or *tab-* root; only during the sixteenth century did the *trom-* and *drum-* words come into use. So much of our drum terminology is onomatopoeic that I believe that the name of the instrument is also and that strokes such as flams, drags, and rolls should not be used in music earlier than the first half of the sixteenth century, but that plain strokes only should be used.'[3]

As with all aspects of early music performance we should never underestimate the skill of medieval and renaissance players, within the limits of their own styles and techniques. Many literary references make one long to know just what medieval percussionists could do given the right opportunity. The French poem *Les Échecs amoureux* (*c.*1370) describes music for a dance at which the instruments were chosen 'Pour le grant noise qu'ils faisoient'. They include:

Trompez, tabours, tymprez, naquairez,
Cymballes, (dont il n'es mes quaires)[4]
(trumpets, tabors, timbrels, nakers, cymbals such as you never heard.)

In the account of medieval percussion instruments which follows, due acknowledgement must be made to the research and writings of James Blades in this field and for a more detailed analysis readers are referred to the relevant chapters of his fascinating book *Percussion Instruments and Their History*.[5] For the sake of convenience all the percussion instruments will be dealt with here, even though two of them – kettledrums and side drum – properly belong to the Renaissance. Most of the instrumental types described are of very ancient origin indeed, drums, rattles, and scrapers being the commonest instruments of primitive man.



## The drum types

Many different types of animal seem to have provided drum heads in the Middle Ages and Renaissance including pigs, goats, and even wolves, though sheep or calf skin was the most common choice. The usual method of fixing the skin to the shell was by ropes attached directly to the skin. This presupposes fairly thick skins at a fairly low tension, otherwise the skins would tend to tear easily when struck. Some pictures show heads nailed directly to the shell, others permanently laced on, either method leaving the instrument rather susceptible to weather changes (drum heads become flabby when damp), but the use of ropes or cords which could be slackened or tightened up afforded some control of tension. The method of rope tensioning which has proved most successful is that still used on certain military drums today: the two drum heads are roped together zig-zag fashion and leather buffs or 'tug ears' are used to narrow the V-formation and tighten the heads. The edge of the drum head was probably often strengthened by being sewn on to a rope ring, but the wooden hoops used in the construction of military drums today were a development of the sixteenth century. Snares, however (usually one or two strands of gut), are regularly illustrated from medieval times onwards on many shapes and sizes of drum including the nakers. Drum sticks reveal a great profusion of shapes both in pictures and in surviving folk-music practice.

### Nakers and tabor

Along with the shawm and the trumpet, the nakers shared the honours in a typical Saracen military band during the time of the Crusades. Europe inherited not only this ancient instrument but the name – *naqqāra* in Arabic – which emerged variously as *nacaires* (French) and *naccheroni* (Italian) as well as the English *nakers*. Marco Polo describes how in 1266 King Kaidu and the great Khan waited for a battle to begin

with the sound of *nacars*[6] and Joinville writing in 1309 about the crusade of Louis IX mentions the terrifying effects of the Saracen *nacaires*.[7] Besides retaining their military association nakers were used for a wider variety of European music including processions and dance music. Players occupied an important place in the royal household from the time of Edward I onwards.[8] Edward III's musicians included four nakerers as well as three taborers[8] and Froissart distinguishes between the two types of instrument when he described the king's victorious entry into Calais in 1347 as 'a foisson de trompettes, de tabours, de nacaires et de buccines'.[9]

The technique of the nakerer involved a pair of sticks and certainly differed from that of the taborer who was basically a one-stick man, whether or not he doubled on a pipe as well. The drums themselves consisted of two hemispherical bowls of about eight inches in diameter. The favourite material was copper although pottery and wood were also used. Many illustrations show the nakers slung round the waist by a strap or belt: sometimes one drum is slightly larger than the other but more often they are the same size. Modern reconstructions suggest that nakers could not be tuned to specific notes and their function must have been rhythmic rather than harmonic. Rope tensioning does make possible a contrast of timbre which is effective, but many medieval nakers must have been permanently laced up like the instruments found in North Africa and India today.

Whilst the nakers may well have afforded opportunities for virtuoso display, the tabor employed a simpler single-stick technique. It was the most popular drum of the Middle Ages and the many variants of its name all stem from the same root: *taberett* and *tabor* in English, *taboret* and *tambour* in French, and so on. Confusion arises over the use of the French *tambourin* for tambourine, string-drum, and tabor and the Italian *tamburino* and German *Tamburin* for both tambourine and tabor. There was no standard shape or size for the tabor as the reader can see for himself if he compares the illustrations from Mersenne's *Harmonie Universelle* with those of the pipes and tabors in chapter 1 (pp 13 and 14). The essential features of the tabor are its cylindrical shape and two drum heads with a snare on the top one, *ie* the one which is beaten. Since only the right hand was used for playing, a small drum could be held by the left hand, though larger sizes were more conveniently slung from the waist. The tabor usually employed the method of rope tensioning already mentioned. As with the

nakerers, taborers found regular employment in the service of the nobility as well as that of the crown: Galpin gives as examples 'the Tabrer of Lady Audham' and 'Guillot the Tabrer of the Earl of Warwick'.[9]

**Kettledrums and side drum**

The beginning of the sixteenth century saw important new developments in the art of drumming. The medieval nakers gave way to the splendour of the larger kettledrums, and the tabor, whilst it continued to flourish as a folk instrument, was rivalled by the side drum with its two-stick technique. Not all these advances in martial music pleased everyone. In his *Musica getutscht* (1511) Sebastian Virdung has this to say about the big army kettledrums of copper, called *tympana*: 'These drums are to the taste of those who cause much disquiet to pious old people, to the sickly and the weakly, the devout in their cloisters and those who have to read, study, and pray. I verily believe that the devil must have had the devising and making of them, for there is no pleasure nor anything good about them.'[10]

The aristocracy, however, took great pleasure in these new delights, which came to Europe once again from the Arab world. In 1457 King Ladislaus of Hungary sent envoys to King Charles of France accompanied by kettledrums on horseback, and according to one Father Benôit, drums of such size had never been seen before.[11] From eastern Europe the kettledrums are included in the famous *Triumph* designed for the Holy Roman Emperor Maximilian I and in 1542 Henry VIII 'sent to Vienna for kettledrums that could be played on horseback and for men who could play them skilfully'.[12]

The shell of renaissance kettledrums was usually made of copper or brass with a diameter of anything between two-and-a-half feet (Arbeau) and seventeen-and-a-half inches (Praetorius). The depth was quite shallow and could be as little as twelve inches. In order to facilitate accurate tuning German makers introduced tensioning screws to replace the old system of rope tensioning. Two hoops are usually employed, one made of wood, the other metal. To the first, called the 'flesh hoop', the drum head is attached by lapping the edges of the drumskin over the hoop. In the second, called the 'counter hoop', which fits above it, the lugs for the screws are fixed. Tuning was crucial to the kettledrum because its role was harmonic as well as rhythmic: to supply a tonic and dominant 'bass' part to the ceremonial fanfares of the trumpet band.

The side drum appeared at the beginning of the sixteenth century and employed the same kind of hoop construction for the drum heads whilst retaining the old rope-tensioning. Unlike the modern orchestral instrument, the renaissance side drum inherited the flexibility of shape and size of its ancestor the tabor. In his *Orchésographie* of 1588,[13] Arbeau illustrates a large side drum about two-and-a-half feet in depth and diameter. And for the first time we get some precise examples of what percussionists actually played. Besides giving us a mine of information about dancing and dance steps, Arbeau prescribes the basic drum rhythms of the dances:

 for the pavan,

 for the basse danse,

and so on. These straightforward 'basic beats' seem more suited to the single-stick technique of the old tabor and they probably represent the sort of thing which taborers had played for centuries. Arbeau also discusses the military uses of the side drum and describes how the player can maintain a clear rhythm for soldiers on the march. He also says: 'In addition to the marches, saltarations, and war dances noted above, the drummer employs a succession of lighter and quicker strokes composed of quavers, combining them with loud blows of the sticks, which resemble the discharge of many arquebuses, and this is done when the soldiers approach near to the enemy.'[14]

The specialized techniques of the side drum, such as the roll, flam, drag, and paradiddle developed in the first instance to fulfil a practical object: to encourage friend and frighten the foe. To this end side drums often accompanied the shrill sound of flutes and fifes, a similar partnership to that of the old pipe and tabor.

**Tambourin and tambourine**

As mentioned in chapter 1, the three-holed pipe was sometimes coupled with other percussion instruments besides the tabor. A combination which remained popular in France long after the Middle Ages and Renaissance was the pipe and string drum. Various names have been used for the string drum including *Scheitholt* and *tambourin* (literally small *tambour*) which also describes the long cylindrical tabor still used in Provence to accompany the pipe. In the fourteenth century it was apparently known as the *chorus* (another confusing name) and had two strings; in the fifteenth century it had three.[15] The nature of the instrument is simple enough and is related to the folk zither. The thick gut strings are stretched over an oblong sound box and tuned to the key-note and fifth of the pipe so as to provide a drone accompaniment. All the strings are struck at the same time with a small stick held in the right hand and the instrument can be suspended from the right forearm. The tambourin was not inseparable from the pipe, however, and during the Middle Ages it no doubt accompanied a variety of instruments.

As already mentioned *tambourin* is also used for the tambourine (Italian *tamburino*, Spanish *panderete*, German *Tamburin* and *Schellen-*

Béarnais string drum, beater, and three-holed pipe. (Pitt Rivers Museum, Oxford)

*trommel*) which we in England called by the less confusing name of *timbrel*. The familiar single-headed frame drum fitted with jingles was introduced into Europe during the Crusades. In the Near East it was often played by women and although European artists often depicted the timbrel in the hands of angels its associations were frankly secular. The playing positions illustrated often correspond with those used in the Middle East today. One hand holds the instrument with the fingers in contact with the skin head whilst the other hand strikes it delicately with the fingers or palm, never the clenched fist. A variety of subtle rhythms are obtained by using the fingers of both hands and the technique is similar to that used on the *darabuka* or hand drum. The Middle-Eastern tambourine has changed little in eight hundred years: the jingles are thicker and heavier than on a modern orchestral instrument and their shape is smoothly concave rather than domed. Praetorius and others before him show us that small pellet bells were sometimes attached as well as jingles. Pellet bells were often attached to accoutrements and clothing in the Middle Ages – saddles, fiddle bows, jesters' caps – and to this day they are worn by Morris dancers, so that their bright sound can make an independent rhythmic contribution to the dance.

### The rommelpot

Here we move into the realm of popular music-making: it is doubtful whether the rommelpot (the Dutch name means 'rumble-pot') was ever regarded as a serious instrument. On the contrary it was obviously great fun, judging by the cheerful expressions on the faces of players depicted by such artists as Frans Hals ('The Man with the Rommelpot'[16]) and Jan Molenaer. The instrument is a type of friction drum. A membrane, such as a pig's bladder, is attached to a suitable receptacle such as an earthenware pot or jug and a stick is inserted through the middle. The action required is not scraping the stick to and fro but rubbing it gently with moistened fingers. The resulting noise has given rise to many of the onomatopoeic names for the rommelpot: *puttiputti* (Italian), *zambomba* (Spanish), and *Brummtopf* (German). In Flanders rommelpots were associated with seasonal rites, especially Christmas celebrations.[17]

## Melodic instruments

The Middle Ages and Renaissance offered much less variety of tuned percussion than that found in the symphony orchestra today. There were three principal types of percussion instrument capable of playing a melody: the xylophone, the dulcimer (already dealt with in the previous chapter), and the chime bells or *cymbala*.

### Chime bells

Bells traditionally occupy an important place in worship and religious ritual of all kinds and there were (apart from the small pellet bells previously mentioned) two main types in use in the Middle Ages. Those with metal tongues or clappers which were used to ring out a merry peal or to summon the congregation to service like the church bells of today lie outside the scope of this book. The other type consisted of a series of accurately tuned cup-bells, usually without tongues, which were regularly illustrated throughout the Middle Ages. They were struck with a pair of small beaters or hammers and were used for musical theory and instruction as well as participating in Church music.

Apart from chime-bells and *clokarde*, a word which came into use about 1400 meaning a set of chime-bells, most medieval names for the instrument are derived from the Latin *cymbalum*. Hence, *cymbal* (English), *cymbale* (French), *Zimbel* (German), and so on. As often happens the name tells you the origin of the instrument: chime-bells are related not so much to the type of church bell just mentioned but to what we call cymbals today. Medieval cymbals (see below) had a high central dome similar in shape to the cup-bells, and both instruments developed from the hollow discs of wood or metal which were struck together in pre-Christian times. In the case of the cup-bells the playing action changed from striking one against the other to striking a whole series of bells with hammers.

Most illustrations show the bells suspended on a simple wooden frame. The number in each set varied from three to as many as fifteen, though the usual compass would seem to have been a diatonic octave c″ – c‴, often with the addition of a flattened as well as a sharpened leading note, b″. For once we have fairly detailed information about compass and construction because bells were a favourite subject for writers and theorists: even the closely-kept secrets of bell metal were regularly revealed as roughly 80 per cent copper to 20 per cent tin.[18] The scientific aspects of bell making with their calculations, proportions, and ratios captivated the medieval mind just as the bright sound of the bells with its clear harmonic make-up captured

the ear. Like the monochord, bells were used for teaching the scale and its intervals, notably in the choir schools. And it was a natural extension of this practice that they should accompany plainsong during the service too. Bells are sometimes depicted hanging by the side of the organ, the only other instrument with an undisputed part in church music. There is definite evidence for the use of bells in certain liturgical dramas[19] and in England they are linked with the performance of the Te Deum.[20] Only the largest sets of bells would have possessed the requisite compass for many chants, but it is quite likely that the player simply changed the octave when the part went outside the range.[21] When bells are accompanying a choir, doubling the voices one or two octaves higher, such a change easily goes unnoticed.

the fact that by the sixteenth century the xylophone was well established. Agricola (1528) shows an instrument with twenty-five bars and Mersenne (1635), though his instruments are more restricted in range, thought that the xylophone was a useful instrument for acoustical experiment. 'Further one can determine what the pitch is of all sorts of bodies by means of these xylophones . . . so as to conclude some new things of their manifest or occult qualities.'[23]

## Other types of instruments

### Cymbals and triangle

The origin of both cymbals and triangle lies in the East. Together with the bass drum they made up in the eighteenth century what was known as 'Turkish Music' – the typical percussion instruments of a Turkish military band – and composers used all three together for special effects (for example Mozart in his opera *Il Seraglio*). Before 1600 neither cymbals nor triangle seem to have had such restricted associations. Their illustrated use ranges from wild Bacchanalian orgies to delicate church music accompaniment in the hands of angels. Whilst the former seems likely enough (we know that the triangle, like the tabor, was used with the three-holed pipe) the latter remains obscure. It is difficult to imagine the contribution which cymbals or triangles could make to the performance of early church music, whether plainsong or polyphony. It was probably their biblical associations which led artists to depict the instruments so often, though the accuracy and consistency of certain details make it clear that these cymbals and triangles were real-life instruments and not vague derivations from classical times. Evidently, as Curt Sachs says of the cymbals, 'though they were never regular implements of European art music, neither were they entirely absent'.[24]

Cymbals are generally shown as being six to ten inches in diameter with a higher central dome than modern orchestral instruments.[25] They were thicker too and the typical playing position was that of ancient cymbals: held horizontally not vertically. The distinctive feature of the triangle (though by no means universal[26]) was a series of rings hanging on the lower bar, linking it with the ancient *sistrum*. Whether such triangles were sometimes shaken like rattles, or whether the rings simply jangled in response to the vibrations created when the instrument was struck with a beater,

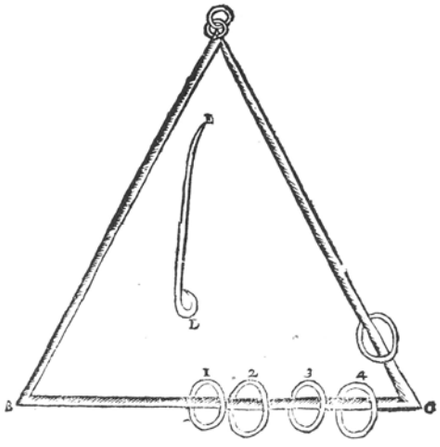
### The xylophone

The first mention of the xylophone comes in Arnolt Schlick's treatise on organ building published in 1511,[22] and the first illustration of it comes in Holbein's *Totentanz* (*c.*1525), pinpointing an association with the macabre which the xylophone has never entirely shaken off. Since it is of such ancient origin and widely known in primitive societies, some simple ancestor of the xylophone was very likely in use in medieval Europe, albeit undocumented. The German name *Stroh-fiedel* (straw fiddle) certainly suggests that this was the case, as does

Triangle and beater, from Mersenne's *Harmonie Universelle* (1636). The instrument is in a typical closed equilateral form. Without an opening at one corner the resonance is effectively damped, making the jingling rings the main feature of the sound. When there is an opening at one corner, however, it is all too easy in performance for the jingles to fall off.



we do not know. But the rings certainly continued to be employed right down to the nineteenth century. Not all medieval triangles were triangular in shape: some were trapezoidal or stirrup-shaped. Mersenne (1635) employs the delightfully confusing name *cymbale* and states that the triangle was used by beggars to accompany the hurdy-gurdy.[27]

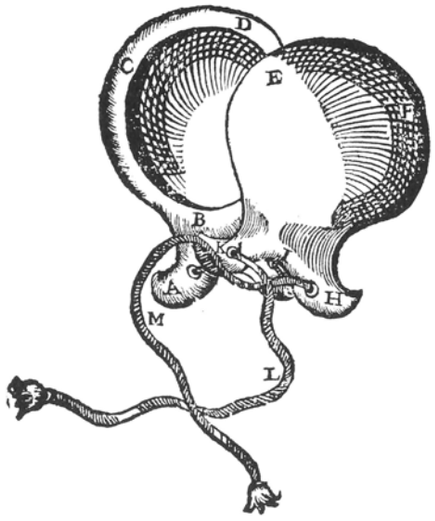
**Clappers, castanets, and rattles**

'All the knuckle bones and the small sticks of wood or other material that one holds between the fingers or in other fashion, and which are handled so dexterously and quickly and with such regulated cadences that it is impossible to explain them, can be related to the castanets and the xylophones.'[28] So writes Mersenne approvingly of a whole range of simple percussion instruments, some of which, like the marrow bones and the cleavers, could be adapted from domestic materials or utensils. Hence Bottom in *A Midsummer Night's Dream:* 'Let us have the tongs and bones.'[29]

The most sophisticated of these wooden clappers were the castanets which probably originated in Spain. In the *Cantigas de Santa María* of Alfonso 'El Sabio' (1232–84) there is a reference to the use of castanets not only in songs but also in Church music.[30] Mersenne says that castanets are 'very much used in Spain where the sarabandes are danced to the sound of the instruments'[31] and like the sarabande castanets spread to other parts of Europe too.

Many of these simpler percussion instruments had a practical non-musical function. Wooden clappers and rattles were used to scare away birds and to provide alarm signals: the old

Castanets, from Mersenne's *Harmonie Universelle* (1636).



policeman's rattle belongs to this tradition. Rattles were associated with various religious customs too and they acted as bell substitutes during Holy week 'when the bells are gone to Rome to be blessed by the Pope'.[32] This particular tradition has survived up to the present century in countries such as Belgium and Czechoslovakia.

**The jew's harp**

No apology is made for following the precedent set by both Praetorius and Mersenne and including the jew's harp amongst the percussion instruments. The classification of this instrument remains elusive, since the action involves a plucking or strumming motion with the hand whilst the variations in tone are produced by altering the position of the tongue and shape of the mouth cavity, which acts as a resonator. The truth is that nobody quite understands how the jew's harp works, let alone how it should be classified, and at least one attempt has been made to classify it as an aerophone or wind-vibrator rather than an autophonic instrument or self-vibrator.[33] Praetorius, rather neatly, classifies it as a 'mixed' instrument.[34]

Equal disagreement reigns over the origin of the name. One explanation is that the jew's harp was a despised instrument and took its name from a despised people ('this instrument serves the lackeys and people of low position', says Mersenne).[35] Another is that *jew's* harp is a corruption of *jaw's* harp, and although this is to some extent borne out by the existence of German name *Maultrommel* (literally mouth-drum) it does seem strange that the name does

not occur until the sixteenth century, a period when the Jews suffered a great persecution in Europe, whereas the instrument itself is as old as the hills. A third and rather ingenious explanation is that jew's harp is a corruption of the French *jeu d'harpe*.[36] A slightly earlier version of the name is *jew's trump* (first recorded in 1545).[37] The French called the instrument *rebube* and later *guimbarde,* whilst Virdung (1511)

uses the name the *Trumpel*. The names with a 'trump' root are perhaps something to do with the instrument's trumpet-like use of overtones or harmonics. Although a jew's harp can produce only one basic note, determined by the length and thickness of the tongue, a skilful player can vary the harmonic structure of the note so as to give a convincing impression of different notes.[38]

# 6 Woodwind

During the Renaissance the development of woodwind instruments was prolific. No other family produced quite as many new varieties nor did other types of instrument proliferate in such a multitude of individual treble-to-bass sizes. One can only marvel at the ceaseless inventiveness and skill of renaissance craftsmen, particularly in Germany, where woodwind instruments were exceedingly popular. The German root of many of the new names – *Krummhorn, Rauschpfeife, Kortholt, Rackett* – suggests a German origin for several of them and the city of Nuremberg in particular was an important centre for the production of woodwind as well as brass instruments. Recorders, crumhorns, and rauschpfeifen as well as trumpets and sackbuts were supplied from Nuremberg to many courts and cities throughout Europe, including the court of the Holy Roman Emperor Maximilian I at Innsbruck.[1] The principal centre for design, however, seems to have been Venice and many of the surviving woodwind instruments of the sixteenth century are of Italian origin.[2] German courts certainly imported from Venice and it is quite likely that the magnificent royal collection built up during Henry VIII's reign[3] contained instruments of Italian origin. A number of Italian musicians turn up in the records of the King's Music[4] for the first half of the sixteenth

century, including Peter de Casanova, Zorzi de Cremona, Vizenzo de Venetia, Ambrose de Myllan, and five members of the Bassani family who remained in the royal service for several generations and have been credited by some writers with the invention of the bassanello, *c.*1600.[5] Makers normally supplied woodwind instruments in complete consorts: the Brussels Museum of Musical Instruments possesses a set of six crumhorns from the second half of the sixteenth century said to have been made for Duke Alfonso II of Este (reigned 1559–97), still nestling in their original custom-made case (see p 49). Because of the lack of standard pitch, buying a ready-made consort was the only way of ensuring that the instruments would play in tune together. Not only that, but the instruments would be voiced in the same way too: many of the problems of balance and intonation in early music ensembles today are caused by the lack of properly 'matched' instruments. Renaissance makers differed considerably in their approach to certain details of construction and both tone and volume must have varied as a result. Although there was a great deal more standardization than there had been during the Middle Ages, it is an over-simplification to talk about 'the' renaissance recorder or 'the' renaissance crumhorn.

As far as materials were concerned, boxwood was the favourite for the smaller instruments and maple for the larger ones. Makers continued to employ a basic one-piece construction: even the largest recorders and shawms were made in this way. The Renaissance witnessed tremendous improvements in the art of wood-turning: most woodwind instruments had to be turned and bored on a lathe, and surviving instruments reveal a high standard of workmanship, with a smooth finish to the bores and very precisely drilled finger-holes. Whereas all woodwind players today hold their instruments with the left hand above the right, during the Renaissance a 'correct' position had not been established, and it was also common to play with the right hand uppermost. On instruments with seven finger-holes, alternative holes were provided for the little finger, offset to the left and right of the other finger-holes. Whichever hole was not required was stopped up with wax. Improvements in metal-work were important too, for the protective bands of metal which reinforced reed-caps and key-covers, and for the development of crooks and keywork. Long S-shaped crooks were essential on the largest shawms, dulcians, and recorders in order to bring the reed or mouthpiece within reach of the player's mouth. Keys, usually of the open-standing type, were added sparingly and again are generally found only on the larger instruments. It was the development of the alto shawm which first made a little-finger-key necessary in order to cover the lowest hole, which was otherwise out of reach of the player's hand. The swallow-tail shape was designed to be operated by either left or right-hand little finger; when pressed down, it closed a metal flap with a sewn-on leather pad. The key was kept in the open position by a brass leaf-spring and the whole mechanism was protected by a perforated key-cover. On shawms and recorders this was a barrel-shaped wooden device known as the *fontanelle:* it simply rested in position and could be slid upwards when required. On crumhorns, curtals, and other instruments whose shape or cross-section made the fontanelle impractical, the key-covers were in the form of a metal box, which could also be easily removed in order to inspect the key mechanism.

Besides the introduction of keywork, the principal innovations of renaissance makers lay in the development of the reed-cap of the crumhorn and its relatives and the use of 'double' or parallel bores connected by a U-bend, as on the various precursors of the bassoon. Perhaps the most striking feature of the renaissance woodwind is their prevailing deepness of pitch. Apart from the soprano shawm, with its brilliant upper register, the chief glory of the reed instruments lay at the bass end of the various families, which often descended to sepulchral regions well below the bass stave. The largest sizes of shawm, curtal, sordun, or rackett added a wonderfully rich sonority to their respective consorts and must have provided a useful means of doubling bass lines an octave lower, a practice recommended by Praetorius.[6]

Very little music was written specifically for woodwind instruments during the Renaissance, although some rare examples will be mentioned during the course of the chapter. Nevertheless, players had a considerable repertory to draw on since most instrumental part-music, especially the dance music, was suitable for a wide variety of instrumentation. The *Danserye* of Tielman Susato, published in 1551,[7] is described on the title page as 'zeer lustich ende bequaem om spelen op alle musicale Instrumenten' (pleasing and appropriate to be played on instruments of all kinds). Anthony Holborne's *Pavans, Galliards, Almans and other short aeirs* (1599)[8] contains the more specific suggestion 'for Viols, Violins, or other Musicall winde Instruments'. Amongst other purely instrumental forms, woodwind instruments are also suitable for canzonas and some of the simpler types of fantasy. Especially on the continent, woodwind instruments also regularly doubled or replaced voices in music of all kinds: *chansons, frottole,* madrigals, and certain types of Church music.

Interesting evidence concerning the professional use of woodwind instruments is provided by a number of sixteenth-century inventories.[9] Henry VIII's Inventory[10] reveals an overwhelming majority of woodwind compared to any other type of instrument: more than seventy flutes, more than seventy recorders, twenty-five crumhorns, twenty-five shawms, thirteen *dulceuses* (a problem: see page 42) as well as bagpipes and a tabor pipe. Other inventories also include a high proportion of woodwind: that of the Accademia

Filarmonica, Verona, 1569,[11] lists several sets of flutes and recorders including a complete chest of twenty-two recorders, two tabor-pipes, five crumhorns, and a curtal. At the Berlin Hof kapelle in 1582[12] there were fifteen recorders, nine flutes, three shawms, seven *Schreipfeifen,* seven crumhorns, and a *Dulzan* (curtal). Pictorial evidence and surviving accounts of performances[13] confirm a wide and varied use of woodwind instruments during the Renaissance: sadly, many of the most delightful instrumental inventions of the sixteenth century enjoyed an active life of less than a hundred years and were swept away by the manifold changes of composition, musical style, and instrumental practice which occurred during the early baroque period. The new dominance of the violin family demanded a range and flexibility which no renaissance woodwind instrument could offer. A glorious period of activity was followed by a decline in woodwind playing until the emergence of the new baroque designs of flute, recorder, oboe, and bassoon from the French workshops of the Hotteterres and others during the later seventeenth century. In each case the most promising member of a large renaissance family provided the prototype for re-modelling: tenor flute, alto recorder, soprano shawm, and bass curtal. Even the bass rackett re-emerged briefly in a new baroque form. But the limitations of the wind-cap instruments precluded further development. With their unchanging tone, fixed dynamics, and inability to overblow, the crumhorn, cornamuse, kortholt, and the rest must have been nearly obsolete by the time Praetorius' *Syntagma Musicum* appeared. With the revival of interest in renaissance music today, however, these instruments are enjoying a new lease of life and are well on the way to becoming more popular and widespread than they ever were during the Renaissance.

## Reed instruments without reed-cap

Little precise information is available about reeds and reed-making during the Renaissance. One of the most useful sources is James Talbot's manuscript,[14] compiled at the end of the seventeenth century, which includes reed measurements not only for the new oboe and bassoon, but for the old shawm as well. Since reeds are so vulnerable to loss or accident it is not surprising that hardly any have been preserved intact from the Renaissance, although the collection of the Kunsthistorisches Museum, Vienna, includes one or two rare examples.[15]

Set of modern rackett reeds mounted on their staples (as supplied by Moeck). Left to right: great bass, quart bass, bass, and tenor.

All the reed instruments, with or without reed cap or pirouette, seem to have employed a similar style of reed. The raw material was the *arundo donax* which grows in the marshes of Spain and Provence and which has been used by reed makers from the time of the earliest reed instruments right up to the present day. The method of manufacture was similar to that used later for bassoon reed-making,[16] though the reeds were shaved much flatter without the central spine typical of the German style of bassoon reed today. Even the smaller sizes of instrument required relatively broad, thick reeds; there was nothing approaching the delicacy of a modern oboe reed with its long narrow blades gouged to twenty-two thousandths of an inch or less.

**The shawm**

Since a confusing variety of names was applied to the shawm during the Renaissance it may be helpful to summarize them as follows:

1. From the Latin *calamus* meaning reed. English *shawm* or *shalm,* French *chalemie* and *chalemele,* Spanish *chirimia,* German *Schalmei* or *Schalmey*. The French word *chalumeau* has been applied to the shawm as well as a detached double-reed bagpipe chanter (Mersenne uses it in this sense) and the single-reed precursor of

the clarinet. The most common meaning of *chalumeau,* however, is a simple rustic reed-pipe (the word is still used in Switzerland in this way[17]).

2. From the Latin *bombus* meaning drone or buzz.
English *bombard, bumbard,* French *bombarde,* German *Pumhart,* and various other corruptions. Agricola (1511) uses *Bombhardt* and Praetorius (1619) uses *Pommer* which became the standard German version of the name. Although *bombard* originally referred to the larger types of shawm (see chapter 1, page 9) the distinction was not always maintained. Praetorius says that shawms are designated by the term *bombarde* or *Pommer* irrespective of their size[18] and the Breton *bombarde* of today is a small folk shawm only a foot long.

3. From the French *hautbois.*
During the late fifteenth century this new name occurs in France. Marcuse[19] interprets it literally as 'high wood' and states that it referred to the higher-pitched shawms. It seems equally likely that the name derived from the shawm's status as one of the *haut* (as opposed to *bas*) instruments and that *hautbois* really meant *loud* wood. In England various anglicized versions of the name occur during the sixteenth century: *hautboys* are regularly called for in the stage directions of plays by Shakespeare and his contemporaries.[20] Most European languages adopted the name for the shawm's descendant, the oboe.

4. From the English *wait,* a watchman.
A common English name for the shawm was the *wait* or *wayte-pipe,* occurring as early as the fifteenth century. During the Renaissance the name *wait* came to mean town bandsman and by extension the instrument which the waits most commonly played: the shawm.[21] In 1530 Palsgrave defines wayte as 'an instrument, hauboys' and as late as *c.*1700 James Talbot describes both treble and tenor waits.[22]

5. Another confusing name may be mentioned here – the Italian *piffaro,* etymologically related to the German *Pfeife* and the English *fife.*[23] In the sixteenth century it was used as a general term for any kind of pipe: specific meanings included *flute* as well as shawm and there has been regular confusion with *piva* (bagpipe).

Unlike its oriental parent, the European shawm of the late Middle Ages and Renaissance employed a broad cane reed which was controlled by the player's lips. On the largest sizes of instrument (from the bass downwards) the reed was placed on the end of a crook, as on the modern bassoon. On the smaller sizes (from the tenor upwards) the reed was placed on a staple, inside a pirouette. Praetorius actually shows the tenor shawm with a short crook *and* a pirouette at the end of it. The pirouette (also used on the renaissance rackett) was a funnel-shaped reed-shield against which the player could press his lips whilst taking the projecting part of the reed into the mouth. The pirouette, made in a variety of shapes, helped to avoid lip-fatigue and offered some protection to the reed. The player placed the reed on the staple so as to suit his embouchure, leaving just the right amount of reed projecting above the rim of the pirouette. The design of the pirouette was an aid to controlled playing, rather than a handicap as is sometimes stated. It is unfortunate that many of the modern reproductions of soprano shawms are made without a pirouette and supplied with oboe reeds. Their emasculated sound is a far cry from the piercing brilliance of the renaissance shawm, the ubiquitous outdoor instrument of its age. 'At great feasts . . . they are to play upon shagbut, cornetts, shawms and other such instruments going with wind' wrote Richard Brathwaite in 1621;[24] the shawms' contribution must have been the most distinctive and by far the most penetrating of the three instruments he mentions. As Anthony Baines says: 'Of all musical sounds that from day to day smote the ears of a sixteenth-century town resident, the deafening skirl of the shawm band in palace courtyard or market square must have been the most familiar.'[25]

Such sounds are still to be heard from the Catalonian *coblas* of north-eastern Spain which play for the *sardana,* the 'national' dance of the region.[26] In bands such as the famous *coblas* of Barcelona which play in the square outside the Cathedral on Sundays, two sizes of renaissance shawm survive, the *tiple* (treble) and *tenora* (tenor). Although they are now fitted out with quite elaborate keywork, added during the last century, the basic design and sound have not changed since the sixteenth century. The *tiple* and *tenora* display the pirouette, the widely conical bore, and terminal bell of the renaissance shawm. Even the reed possesses the flared shape illustrated by Mersenne and others. The effect of a dozen or so *tiples* and *tenoras* playing together is thrilling and even though their repertoire of nineteenth-century marches is so different from that of the renaissance bands they provide a direct link with the playing traditions of four hundred years ago. Northern Spain is also the home of another interesting shawm survival: the *dulzaina,* found all over the northern part of the country, is a small keyless shawm, played without a pirouette. Typologically it is derived from the bagpipe chanter, like the Breton bombarde, and must have been relatively rare during the Renaissance, although Mersenne illustrates an instrument of this kind. Despite the absence of a pirouette, the dulzaina still produces a very penetrating sound.

A feature of all shawms is a number of vent holes, variously placed between the little-finger-hole (or key) and the end of the bell. This section of the bore is often quite extensive, occupying more than half the overall length on some instruments, and it makes an important contribution to the tone and carrying power. It may also have prompted the addition of three extra keys on the larger shawms to extend the range downwards by three diatonic notes. On the bass shawm pitched in F, for example, the little finger operates two keys instead of one,

giving F and E respectively when closed. D and C are obtained by closing two thumb-keys at the back of the instrument. The key mechanism for all four holes is protected by a very large fontanelle. With the crenellated metal band commonly found round the bell, the shawm was altogether a fairly tough instrument capable of standing up to the exigencies of outdoor life. On occasions the wear and tear must have been considerable. Anthony Baines[27] mentions a dispute amongst the town bandsmen of Augsburg which reached its climax when one of them aimed a blow at the bandmaster's son's head with a bass shawm.

Praetorius describes the full range of renaissance shawms in his *Syntagma Musicum* and makes clear certain peculiarities of the family. From the bass upwards (*see figure*) shawms were built in sizes a fifth apart: tenor in C, alto in G, soprano in D, and a *Kleindiscant* in A. No doubt, the fact that the smaller shawms were pitched in sharp keys was useful when they played with cornetts as was the regular practice in the town or royal bands. But when a whole band of shawms played together there was a problem, as Praetorius observes: 'it becomes difficult to match them all together in intonation; for the outermost instruments of the set are then separated by five fifths, a relationship very difficult to deal with'.[28] In other words, whatever key the piece was in, it would necessarily be uncomfortably far from the basic scale of one or two members of the family. In practice shawm bands (or the more common 'mixed' band of soprano shawm, cornett, two alto shawms, tenor sackbut, and bass shawm[29]) normally played their music a tone higher than written. This transposition was mainly to accommodate the soprano shawm which at the bottom of its range lacked the c′ found in most soprano parts and on which f′ was an unsteady note of poor quality. Praetorius sensibly suggests[30] that makers should produce two much-needed sizes of shawm, a tone lower than the standard models – *ie* an alto in F and a soprano in C. Whilst his advice does not seem to have been heeded at the time, modern makers have followed it to such an extent that today instruments built in the original key are very hard to come by. It should be noted that, in England and France at least, the nomenclature of the two original shawm sizes was rather at

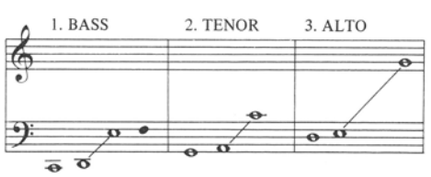
variance with that of other instruments. The *treble* shawm meant the soprano in D – not the alto as we should expect – whilst the *tenor* shawm referred to the alto in G. Together with the bass, they seem to have been the sizes most regularly used.[31]

During the later seventeenth century a narrow-bore type of shawm was developed in Germany and the Low Countries known as the *Deutsche Schalmei* or *Schalmey*. It represented an attempt at compromise between the old shawm and the newly developed oboe. But no compromise was really possible since the oboe represented an entirely new line of development

from the shawm and fulfilled a quite different purpose. It is worth noting that, versatile as the oboe is, it has never been much use as a band instrument in the open air, where the shawm's vastly superior carrying power is desirable.

**The bassanello**

Nearly a century before the appearance of the baroque oboe there seems to have been some attempt to tame the extrovert brilliance of the shawm. In 1577 in an inventory made of the estate of the Archduke Karl of Austria there occurs the first mention of the *bassanello*.[32] Praetorius tells us that this was a soft version of the shawm, invented by and named after the Italian composer Giovanni Bassano.[33] A number of scholars find Praetorius' attribution suspect: Curt Sachs[34] thinks it unlikely for chronological reasons (the first known date in Bassano's life is 1585) and points out that it was not until the nineteenth century that the practice of naming instruments after their inventors became established. Other writers,[35] however, have credited the members of the Bassano family resident in England with the invention. If this were the case, however, it does seem strange that the instrument is only mentioned in German sources. Unfortunately there are no surviving examples and for our most detailed information we must rely on Praetorius, who gives the following sizes:



Bassanello ranges from Praetorius' *Syntagma Musicum*.

All the bassanelli have the reed set on a crook and seven finger-holes (with a little-finger-key for the lowest) but no thumb-hole. The overblown range was evidently quite useful: Praetorius says that 'with good reeds, bassanelli can be brought quite high'.[36] He particularly recommends the sound and pure intonation of the smallest bassanello and says it is very suitable for tenor parts in mixed ensembles. Praetorius' illustrations show instruments with a delicately expanding conical bore and an amount of bulbous turned decoration which is surprising for the period. Altogether the bassanello is a rather intriguing instrument and well worth some attempt at reconstruction today.

There may possibly have been some kind of 'soft' shawm in existence in England at the beginning of the sixteenth century. In the Lord Chamberlain's Records for 1509 there is a reference to liveries for nine players of 'The styll shalmes'.[37] This was before the arrival of the Bassano family, however, and there is no reason to suppose that still shawms, whatever they may have been, were identical with bassanelli.

**The curtal or dulcian**

Although it is such a splendid instrument to look at, and is certainly ideal for playing the bottom part in a renaissance wind band, the bass shawm suffers from several serious disadvantages. It is heavy to hold, cumbersome to carry about, and although the fundamental range up to f is full and secure the overblown register is disappointingly weak and wheezy, fading out altogether above the note C′. Dissatisfaction with the bass shawm led to its gradual replacement by the bass curtal, a much more handy and versatile instrument. Of all the sixteenth-century woodwind innovations, the development of the double-bore principle (two parallel tubes drilled in the same block of wood and connected by a U-bend at the bottom) has proved of the most lasting value. It is all the more frustrating that we know so little about where the earliest developments took place, and we cannot even be sure that the curtal was the first double-bore instrument to be produced. Anthony Baines[38] points out that the embryo of the bassoon can be seen in certain early types of bagpipe on which some kind of doubling back of the tube is quite common. On surviving examples from Bohemia and elsewhere there is a thick section of the long drone pipe which contains three parallel drillings joined alternately top and bottom to produce a flattened S shape.

This saves a foot or more in the overall length of the drone and may, as Anthony Baines suggests, have provided the impetus for the double-bore experiments of the sixteenth century. Since the bagpipe drone is cylindrical, however, it is possible that the earliest double-bore instruments may have been cylindrical also. It is much easier to drill a pair of cylindrical bores than to ream out a pair of conical ones and it is tempting to wonder whether the *dulceuses* described in Henry VIII's Inventory[39] as *short* instruments may have been some kind of *cylindrical* double-bore prototype. This is pure conjecture, however. The first real evidence is for the conical-bored curtal from about 1540 onwards. An early mention comes in 1546 when the Verona Academy bought a *fagotto* and a *dolzana* from a soldier:[40] although the meaning of these names is ambiguous at this stage, one of them must have meant a curtal.[41] In 1562 the Verona Academy lists a *Fagoto* with its reeds and by 1585 there were *fagotti*. Amongst the Flemish Band of Marie, widowed Queen of Hungary, two *fagotes* are listed in 1559. The earliest English reference comes in 1574 in the Household Accounts of Sir Thomas Kytson of Hengrave Hall, Suffolk: '1574 Dec. For an instrument called a curtall XXXs'.[42] The following year a double curtal was in the possession of the Exeter Waits. By the last quarter of the century the curtal had established

a regular place for itself in the town bands. The Corporation of the City of London bought one in 1597 and several continental bands are pictured with the bass curtal playing alongside cornetts, shawms, and sackbuts. In about 1582 Stephen Batman wrote: 'The common bleting musicke is the drone, hobuis and curtoll' (*ie* bagpipe, shawm, and curtal).[43] But unlike the shawm the bass curtal was not solely restricted to being a band instrument. It was useful for doubling the bass line in church music – hence the name *Chorist-Fagott* – and it had a role to play in court music too. In 1589, at the wedding of Duke Ferdinand of Medici to Christine of Lorraine which took place in Florence, one of the interludes was accompanied by 'Tromboni, cornetti, dolzaini et fagotti'.[44]

Much of the early evidence for the curtal's existence comes from Italy, as do a number of the earliest surviving instruments, and it is likely that the initial development took place in Italy. At any rate, Italy was the home of a unique experiment which contributed one of the curtal's family names – *fagotto* – and may have contributed to the development of the double-bore principle in general. Before the year 1521 a certain Canon Afranio of Ferrara (*c.*1489–*c.*1565) was already experimenting with an instrument which he called a *Phagotum*, employing a pair of U-tubes. At a banquet in Mantua in 1532 the Canon played a solo on 'il suo fagoto' and an illustrated description of the phagotum was published in 1539.[45] Together with a sheet of playing instructions dated 1565 this provides comprehensive information[46] about one of the most extraordinary musical inventions of the sixteenth century, sufficient for a convincing modern reconstruction to be made.[47] Because of the amount of information available, the phagotum has been regularly mentioned in reference books, but because of its name it has often been misunderstood as a kind of bassoon prototype. The phagotum was, in fact, a kind of bagpipe and the only feature it shared with the curtal was the use of parallel bores. Following Lyndesay Langwill,[48] we may contrast the features of the two instruments as follows:

| *Phagotum* | *Curtal* |
|---|---|
| Bellows-blown | Mouth-blown |
| Single reeds made of metal | Double reeds made of cane |
| Twin U-tubes, *c.*22 inches high | Single U-tube, *c.*4 feet high |
| Cylindrical bore | Conical bore |

On the instruction sheet of 1565 the word *fagoto* is used to describe each of the larger pillars of the phagotum with their parallel bores and by this date the word was already being used for the curtal.

From what has already been said, the reader will have observed that not only is the evolution of the curtal a rather obscure subject but that it is further confused by the variety of names which are applied to the instrument. As with the shawm a summary may be found helpful.

1. From Canon Afranio's *phagotum*.
Italian *fagotto*, German *Fagott*, Spanish *fagote*.
The name *phagotum* represents a Latinization of the Italian *fagotto* (a bundle of sticks) and was presumably applied to Afranio's instrument by way of a nickname. The one-piece curtal could in no way be said to resemble a faggot or bundle of sticks, and must presumably have derived the name *fagotto* from the *phagotum*.

2. From the Latin *curtus* (= short).
English *curtal*, sometimes spelt *curtoll*, *curtail*, and other variants.
This was the main English name for the instrument, and like *bombard* it was borrowed from artillery: *curtal* had previously denoted a type of short-barrelled cannon. The continental equivalents, however, *courtaut* (French) and *Kortholt* (German), referred to cylindrical types of double-bore instrument, not the curtal.

3. From the Latin *dulcis* (= sweet).
German *Dulzian*, English *dolcian*, Italian *dolzone*, and other variants such as *dolzan*, *dulcan*, *dolcan*, etc. This name, particularly common in Germany, is confusing because of its similarity to the mysterious medieval *douçaine* and the equally mysterious *dulceuses* of Henry VIII's Inventory. To make matters worse the *dulzaina*, which is mentioned several times

during the Renaissance, was evidently a cylindrical instrument with a single bore, like the cornamuse, despite its use today for the small keyless shawn of Northern Spain.

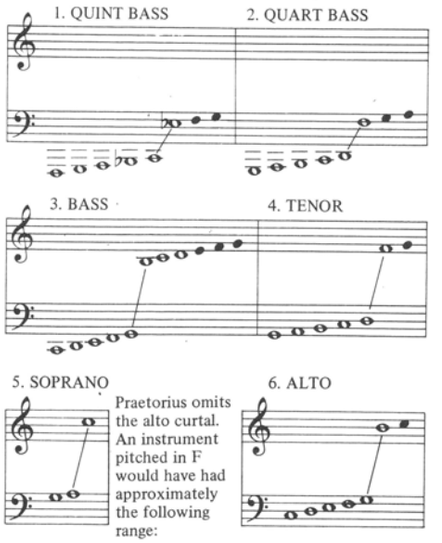
4. From the Latin *bassus* (= bass).
French *basson*, Spanish *bajon*, Italian *bassone*, English *bassoon*.
This name has been in use since the early seventeenth century, though it did not come into regular use in England until the following century.

It is worth noting that up to the mid-seventeenth century, all these names referred to the curtal. After the emergence of the bassoon proper they were indiscriminately applied to the new instrument as well as the old: by the eighteenth century so great was the confusion that the word *Fagott* was even used for the old bass shawm.[49] In churches and town bands the curtal continued to be used throughout the baroque period: the Denner workshop in Nuremberg produced some very fine curtals[50] as well as examples of the new baroque woodwind.

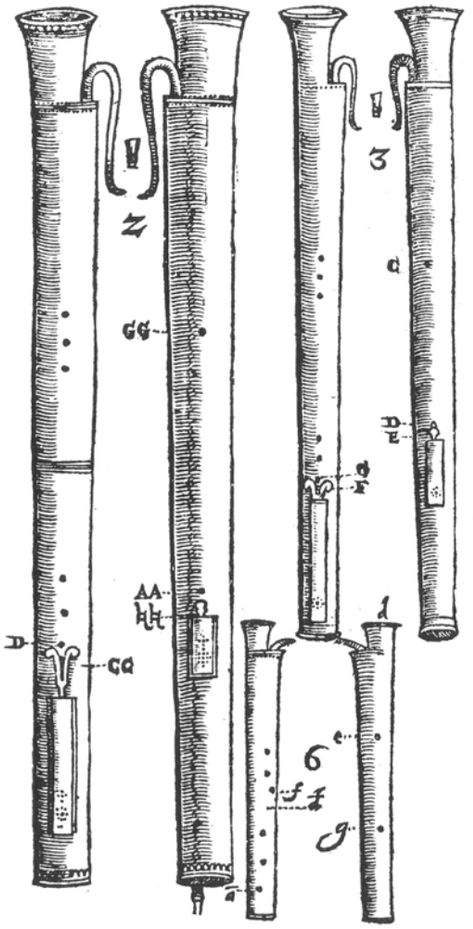
A variety of names were used to distinguish the different sizes of curtal. As already mentioned the most common size was the bass, known in England as a *double* curtal and abroad as a *Chorist-Fagott* or *fagotto chorista*. The prefix *double* on the continent, however – as in *Doppelfagott* or *fagotto doppio* – referred to an instrument pitched a fourth or fifth lower than the bass curtal. Diminutions such as *fagottino* or *bajoncillo* signified smaller sizes, like the English *single* curtal.

Despite the plethora of new names, the curtal still retained much of the shawm's basic design, re-formed into a U-tube. The bore followed the widely expanding conical bore of the shawm and the tone was still rather bottom-heavy: to lighten the quality of the lower notes some curtals were made with a perforated bell-cap, looking rather like a pepper-pot, which acted as a mute. Such instruments were known as *gedäckt* (covered) and Praetorius says that the tone is 'much less strong and considerably softer and lovelier'.[51] Some of the overblown notes in the second octave (g upwards on the bass) are rather unsteady and uneven in tone, but can be 'humoured' by using special fingerings involving the thumb-holes, and the bass curtal can ascend as high as g′, giving it a useful range of two-and-a-half octaves. The tone has a 'dolce' quality compared to the shawm as the name *dulcian* suggests. There are two keys, the standard one for the little finger and a thumb-key (for low E on the bass). The lowest three notes, governed by the thumbs only, are much more manageable than on the shawm with its clumsy extension keys. The two bores, reamed out in opposite directions, are connected at the bottom by a small passage cut between them and sealed at the base with a wooden (later cork) plug. Some of the larger curtals were made in two halves like the cornett so that the bore could be very carefully finished off: the twin channels are gouged out, the two sections glued together and finally bound round with leather.

Praetorius gives the following sizes of curtals:



Curtal ranges from Praetorius' *Syntagma Musicum*.



Praetorius makes enthusiastic mention of an even larger curtal – a great bass, lying an octave below the ordinary bass and descending to C′, which he says is still under construction by Hans Schreiber, one of the Electoral chamber musicians at Berlin. 'If he should succeed in this,' writes Praetorius,[52] 'he will indeed have produced a unique and remarkable instrument: for even on the organ it is often difficult to construct the two lowest notes of the largest trombone stops – the 16 foot C and D – so as to sound quite pure. But time will tell.' Whether Hans Schreiber ever completed his great-bass dulcian is unknown: but such an instrument has been produced today by Rainer Weber of Bayerbach and it fully lives up to Praetorius' expectations.

It has been stated that the smaller curtals, especially the soprano and alto, are weak and deficient in tone. Whilst it is certain that the smaller sizes were much less common than the bass, and surviving specimens are comparatively rare,[53] practical experiment reveals that these midget curtals (as Anthony Baines affectionately calls them) have a resonant reedy sound with a character all their own, and their size lends itself to dexterous fingerwork. The idea of a

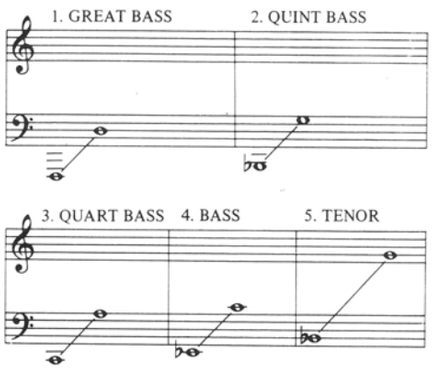
consort of curtals playing *en famille* cannot have been unknown in the Renaissance: indeed, some kind of tradition seems to have been carried on into baroque and classical times. A surprising number of tenoroons and octave bassoons were made during the eighteenth century and at least one piece of ensemble music survives for them.[54] There is, alas, no such specific repertoire from the Renaissance, although during the first half of the seventeenth century a number of composers included the bass curtal in compositions for both church and chamber,[55] amongst them Michael Praetorius, Giovanni Gabrieli, and Heinrich Schütz. The earliest solo work is the *Fantasia Basso solo* (bass curtal plus continuo) by Fray Bartolomé de Selma y Salaverde, published in Venice in 1638. Bartolomé – a Spanish curtal-playing monk – was in the service of the Archduke Leopold of Austria, and if this composition is anything to go by he must have been a virtuoso player, with a brilliant finger technique and mastery of the complete compass of the instrument. The fantasia descends several times to low B♭ and by this date a bell extension and third key had been introduced in France. Mersenne (1635) describes the *basson* as having *three* keys and illustrates an instrument with extended bell. Anthony Baines has suggested that this extension came about in order to accommodate the cellos in Louis XIII's court band, which were tuned a tone lower than normal.[56]

**The sordun and courtaut**

As has already been mentioned, it is easier to drill cylindrical bores than conical ones, and so it is not surprising that renaissance makers experimented with narrow *cylindrical* double bores. A cylindrical bore has an additional advantage, in that it permits the instrument to be made still shorter; when sounded with a reed it has the acoustical properties of a stopped pipe and produces a scale an octave *lower* than on the equivalent length of expanding conical bore. So whilst a bass curtal is roughly half the length of a bass shawm, a bass sordun or courtaut is half as short again. The tone is much softer and more muffled, however, and very similar to that of a rackett: hence the other name given to the instrument, *sordone* (Italian), *Sordun* (German), *sourdine* (French), all derived from the Italian *sordo*, mute. The sordun has no bell; the sound simply emerges from a rather insignificant lateral hole at the top end of the instrument near the crook.

The sordone is first mentioned by Zacconi in 1592[57] and an inventory made in 1596 at Schloss Ambras near Innsbruck enumerates two basses, three tenors, two descants, and one 'smaller' descant.[58] Four of these have survived and are now housed in the Kunsthistorisches Museum, Vienna; the larger sizes reveal a system of keywork uniquely elaborate for the period. The sordun described by Praetorius is much simpler: the instruments he illustrates are keyless, though he says: 'Sorduns have twelve visible holes – and some have two keys as well. Besides these there is a hole below for moisture and one on top from which the sound issues.'[59] Of the twelve finger-holes, eight employ the standard woodwind fingerings using the thumb, six fingers, and little finger whilst others (for the lowest four notes) use the remaining thumb and little finger as well as the middle joints of each index finger. Praetorius gives the following sizes of sorduns (*overleaf*):



Sordun ranges from Praetorius' *Syntagma Musicum*.

Mersenne[60] shows yet another design of sordun – under the name *courtaut* – equipped with six short projecting tubes which he calls *tetines*. These are to help the player locate some of the remoter holes, a particularly tricky business with the holes governed by the middle joints. Mersenne's courtaut was designed for left- or right-handed players and the unwanted *tetines* had to be stopped up with wax. Because of its cylindrical bore the sordun should theoretically be able to overblow at the twelfth (as the clarinet does). The bore is too narrow for any overblown range to be at all successful, however, and in practice the instrument is restricted to the fundamental notes.

**The rackett**

The ingenuity of renaissance makers was not content with a mere pair of parallel tubes and in the rackett produced the *ne plus ultra* of multiple-bore construction. Once again the ingenious inventor remains unknown though the instrument is likely to be of German origin. The first reference to it (as *Raggett*) occurs in Württemberg inventories of 1576 followed by a Graz inventory of 1590 which includes *Rogetten*.[61] The well-known painting of the Munich court band in the time of Orlando di Lasso[62] (1532–94) shows a rackett player amongst a delightful mixed consort which also features flute, recorder, cornetts, sackbut, lute, viols, *viole da braccio*, and harpsichord. Another depiction is to be found in the outstandingly beautiful ivory cabinet by Christof Angermair (*c.* 1600–32), carver at the Munich court (see p 39). A number of racketts survive in museums at Vienna, Munich, Leipzig, and elsewhere.[63]

The rackett's narrow cylindrical bore consists of no less than nine parallel channels drilled in a wooden or ivory cylinder and connected alternately top and bottom. The wide reed is inserted into a pirouette similar to that of the shawm and the outlet of the bore is a small lateral hole at the base of the instrument. Because of the internal convolutions, the size of the rackett is amazingly tiny compared to its pitch. The smallest size, the tenor (with a bore of only 6 or 7 millimetres), is a mere four-and-a-half inches in height: yet its lowest note is the G on the bottom of the bass stave. The great-bass rackett descends as low as the double-bassoon in spite of being only just over a foot high. It is surprising how full and reedy a consort of racketts can sound, despite the constrictions of the narrow bore and multiple U-bends. Praetorius was rather disparaging about the effect of a complete *stimmwerk*: 'In sound racketts are quite soft, almost as if one were blowing through a comb. They have no particular grace when a whole set of them is used together; but when viols da gamba are used with them, or when a single rackett is used together with other wind or stringed instruments and a harpsichord or the like, and is played by a good musician, it is indeed a lovely instrument. It is particularly pleasing and fine to hear on bass parts.'[64]

Rackett ranges from Praetorius' *Syntagma Musicum*.

The painting and sculpture already mentioned confirm the German practice of using a single rackett in a mixed ensemble and the larger racketts are very effective when doubling the bass line an octave lower. Praetorius seems to have had a particular interest in woodwind instruments which operated at 16-foot pitch. He says: 'I myself designed and recently had constructed a rackett which can be brought down to the 16 foot C, and which in its lower register is similar to the largest diapason stops of the organ.' Of course, when playing in consort the whole rackett family operate at 16-foot pitch, an octave *lower* than standard instruments, just as the smaller sizes of recorder operate at 4-foot pitch, an octave *higher* than normal.[65] Praetorius states that racketts, like sorduns, are not readily overblown, although a good player can obtain one or two 'falsetto' notes on a good instrument.

The various names for the rackett derive from its squat appearance and convoluted bore. The German *Rankett* and other variants already mentioned are usually derived from the old German word *rank* meaning crooked. Anthony Baines[66] has suggested that since the rackett does resemble a small firework, the derivation may be from *Raquete* (a rocket). Later German names were *Wurstfagott* (sausage-bassoon) and *Faustfagott* (fist-bassoon). The Italian *cortali* denoted racketts and the Italian *cervellato* (sausage) provided the most common French name *cervelat*, sometimes spelt *cervelas*.

Since a number of modern writers[67] describe the renaissance rackett but illustrate its baroque descendant the later history of the instrument may be briefly mentioned here. During the later seventeenth century the bass rackett in F was entirely redesigned. It was given a wider expanding conical bore instead of a cylindrical one, a coiled crook inserted at the side of the instrument instead of a pirouette, and a centrally placed bulbous bell to enhance the tonal projection. The disposition of finger-holes, very wayward on renaissance racketts, was entirely rationalized and a number of *tetines* (presumably derived from the sordun) were added to facilitate the fingering. The result was in effect a compact narrow-bore bassoon, light in tone and enchanting in appearance. The development of the baroque rackett (effective range B♭′ – f′ or g′) has been attributed to the Nuremberg maker J. C. Denner (1655–1707) and an instrument from his workshop (dated 1709) survives in Vienna.[68] According to Sir John Hawkins at least one rackett was produced in early eighteenth-century London, though this may have been an attempted reconstruction of the renaissance type. The maker was Thomas Stanesby, famous for his recorders, flutes, oboes, and bassoons. Hawkins's account is so amusing as to warrant quoting in full.

'Stanesby who was a diligent peruser both of Mersennus and Kircher, and in the making of instruments adhered as closely to the directions of the former as possible, constructed a short bassoon or Cervelat . . . for the late earl of Abercorn, then Lord Paisley, and a disciple of

Dr Pepusch, but it did not answer expectation: by reason of its closeness the interior parts imbibed and retained the moisture of the breath, the ducts dilated, and broke. In short the whole blew up.'[69]

Whether in its cylindrical or conical version, the rackett is quite a tricky instrument to make.

The finger-holes have to be drilled often quite deeply at a variety of different angles in order to join up with the appropriate section of the bore. Because of the depth of some of the finger-holes fine tuning is more difficult than on most woodwind instruments and great care must be taken to seal all the U-joints. It would be so much easier if the instrument was made out of a section of cylindrical *metal* tube which could be bent into any shape you fancy. Such an idea must have crossed the mind of the maker of the *Tartölde* listed in the 1596 inventory of the music room of the Archduke Ferdinand at Schloss Ambras and now in the Kunsthistorisches Museum, Vienna.[70] These unique instruments are basically racketts (not shawms as sometimes stated) made out of coiled brass tubing concealed inside a painted brass dragon. The looped brass crook is designed for a reed without pirouette, and unlike most racketts, the internal structure has escaped the ravages of time so that the *Tartölde* are still in playing condition.

## The reed-cap instruments

All the instruments so far mentioned in this chapter demand a similar expertise in playing to that of the modern oboe or bassoon. The player must develop the correct embouchure for his instrument and learn how to control the reed so as not only to make some gradation of tone and dynamics but to be able to adjust his intonation to the ensemble in which he finds himself and assist the weak or out-of-tune notes on his instrument. The basic scale of any renaissance reed instrument should be in tune with itself, but the chromatic notes can only be obtained by cross-fingering which tends to weaken the tone and often produces one or two unsteady notes requiring 'humouring' on the player's part. On instruments pitched in C, for example, the fingerings for A♭, F♯, and E♭ in the basic scale can be rather unsatisfactory, though the professional players of the Renaissance certainly overcame any such shortcomings as a matter of course. However, in the days when musicians were expected to double on a variety of instruments (and in the courtly entertainments already mentioned quite a bit of doubling must have gone on) it was useful to have instruments which did not require the mastery of a special embouchure. From the late fifteenth century onwards there developed a new genre of woodwind instrument in which the reed was kept out of contact with the lips by means of a reed-cap. The player simply blows through a slot in the top of the cap, using a fairly strong breath pressure in order to activate the reed which is mounted on a staple and vibrates independently as on the bagpipe. The reed-cap, which survives today on the bagpipe practice chanter, represents an extension of the principle of the older hornpipe and bladder-pipe, though all the renaissance reed-cap instruments employed double, not single, reeds. It must not be imagined that once the reed is hidden away inside a reed-cap all the player's troubles are over. Cane reeds fluctuate wildly with changes in temperature or humidity and require careful maintenance on reed-cap instruments just as they do on bagpipes. Even when equipped with plastic reeds, as on most modern reproductions, reed-cap instruments are by no means easy to play in tune. But with a well made and well regulated reed, the problems are a lot easier than on the shawm or curtal. Most reed-cap instruments cannot overblow at all and have a very restricted compass. This usually means that with only one octave to cope with the finger-holes can be placed so as to assist the chromatic notes: on the cylindrical-bore reed-cap instruments such as the crumhorn, cross-fingerings work extremely well. Since their pitch is governed entirely by breath pressure, reed-cap instruments play at a fixed dynamic level: any fluctuation in pressure produces an equivalent change in pitch. Tonguing through a reed-cap produces a characteristic sharp attack which is very effective in an ensemble. A consort of crumhorns, *cornamusen*, or *rauschpfeifen* produces a fresh, invigorating sound quite unlike any other. The nearest sound is, of course, that of the renaissance organ, so many of whose stops were modelled on the sounds of contemporary woodwind instruments. But when each line in a consort is played by a different instrument, there is a much greater separation than on the organ, and the human breath imparts a living quality which the organ's bellows cannot quite match.

### The crumhorn

The earliest and by far the most common of the reed-cap instruments was the crumhorn. The name first occurs in 1489 as an organ stop in Dresden,[71] suggesting that the instrument had already been in use for some time. The name means literally 'curved horn' and is associated with the old English *crump* and the German *krumm* meaning crooked. Hence *Krumbhorn*, *Krummhorn* (German), and the French *cromorne* (not met with till the seventeenth century).[72] Other names used for the instrument also refer to its shape: *tournebout* (French), *corno torto* or simply *storto* (Italian), and *orlo* (Spanish). In Italian usage *piva* and *cornamusa* both referred to the crumhorn as well as the bagpipe.[73] The crumhorn is made by turning and boring a length of boxwood and then steaming round the lower end to produce the characteristic fishhook shape. The curve has no effect on the sound whatsoever and is purely decorative: presumably it was inherited (like the suffix *horn*) from a medieval crumhorn/bladder-pipe prototype, which had a curved horn-bell like the hornpipe. It is easy to see how the crumhorn

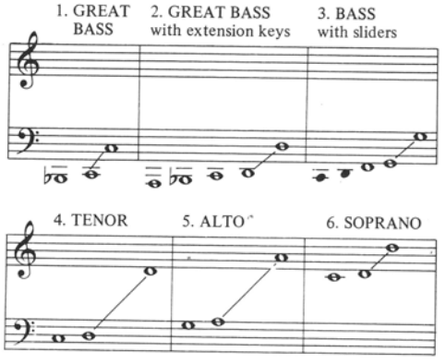
developed from the bladder pipe: the rather vulnerable bladder could easily become damaged and players simply learnt to do without. Apart from the bladder itself the two instruments seem to have been very similar by Virdung's time (1511) with a cylindrical bore, six finger-holes, and a slightly funnelled-out bell. Although they are not shown, there must have been one or two vent holes in each bell section, otherwise the instruments would have produced a very peculiar scale. Virdung shows four sizes, as does Agricola (1538), and Praetorius gives the following:



Crumhorn ranges from Praetorius' *Syntagma Musicum*.

Modern alto crumhorn in F by Moeck, with two extra keys for high a′ and b♭′. (Author's collection)

In spite of the fact that Praetorius states that crumhorns had *six* finger-holes plus thumb-hole, his own illustrations reveal seven finger-holes. In his usual practical way, Praetorius was conscious of the restriction imposed by the crumhorn's basic octave-and-a-note compass and in Volume III of his *Syntagma Musicum* describes how crumhorn players should transpose music to use their resources to the best advantage.[74] Since bass parts tend to have the widest range, the largest crumhorns were often equipped to cope with additional low notes. One method was to fit two keys for the little finger instead of one: the vent-holes were provided with brass sliders to pre-set the pitch of the extra (lowest) note when both keys were closed. Praetorius' *Bass Clʰorist* is of this type. Alternatively, as with Praetorius' great bass in C, crumhorns were fitted with three extension keys like those of the larger shawms. However, there are no surviving examples or illustrations with extension keys for the *upper* end of the register such as are fitted by most modern crumhorn makers.

The standard four-part consort of crumhorns was not soprano, alto, tenor, and bass as we might expect but alto, two tenors, and bass; furthermore the alto was pitched in G, as Praetorius shows, a tone higher than most altos made today. It is a pity that in the modern revival of early instruments an unwritten law seems to have grown up stating that everything that blows shall be in either C or F; there really is a need for G and D instruments too, alto recorders and crumhorns in G being particularly useful. As far as crumhorns are concerned, the soprano in C seems to have been a comparative rarity: few such instruments have survived, neither Virdung nor Agricola mentions a smaller size than the alto in their texts[75] and Praetorius gives his alto the name *cantus*. By virtue of its narrow bore the soprano crumhorn does tend to be a rather weak instrument, deficient in tone: the alto makes a much better 'lead' instrument for a consort. A surprising amount of music fits the a.t.t.b. consort as it stands,[76] including the pavan marked specifically for 4 crumhorns from Johann Schein's *Banchetto Musicale* of 1626 and the majority of Susato's *Danserye* of 1551. Although Susato does not suggest using crumhorns in his edition, the fact that he opened up his music shop and printing business at the sign of 'In de Kromhoorn' suggests that he had a particular affection for the instrument. Other works associated with crumhorns include:

1. The six-part madrigal *Guardan almo pastore*[77] by Francesco Corteccia, from the Medici wedding celebration of 1539, which was first played by cornett, soprano crumhorn (*stortina*), and four other crumhorns (*storte*), and then sung by six shepherds, doubled by the same instru-

ments. A similar combination was used in Corteccia's music to the Florentine *intermedii* of 1465; the third *intermedio* features a *cornetto muto* and five *storti* accompanying voices.[78] On this occasion the composer seems to have had a particular dramatic effect in mind, since the voices represented Frauds and Deceptions. Elsewhere in the intermedii the nasal buzz of crumhorns seem to have been employed as a special effect; three crumhorns helped to celebrate the Age of Bronze in 1548[79] and one accompanied Calumny, Ignorance, and Fear in 1468.[80]

2. The six-part psalm setting *Erzürne dich nicht*[81] (1526) by Thomas Stolzer. In a letter he recommends that it be played on *Khrumphörner* 'since it suits them throughout, which is not the case with every composition, especially those in many parts'.[82]

3. The five-part *Pazzamezze* and *Gaillarde* (nos CCLXXXIII and CCLXXXIV) from Praetorius' *Terpsichore* (1612)[83] These two dances by F.C. (=Francisco Caroubel) are mentioned by Praetorius in his introduction[84] as being suitable for *Krumbhörner* or other instruments. Curiously enough they not only require drastic downward transposition but some adjustment of the inner parts as well since all three exceed the 9-note range. Professional woodwind players in those days must have been fairly adept at 'editing' their parts as they went along in order to suit the compass of their instruments.

4. A number of anonymous works in a set of part-books now in the Royal Danish library in Copenhagen which seem to have been compiled in mid-sixteenth century for the wind band of Duke Albrecht of Prussia.[85] The outstanding piece is a splendid five-part setting, basse-danse style, of the popular Flemish tune *Tandernaken*, scored for a.t.t.b.b.[86] Some of the other pieces require the downward transposition mentioned by Praetorius before crumhorns can be used. Such transposition facilitates the performance of a wide variety of dances and chansons not specifically intended for crumhorns.

As Bernard Thomas has pointed out,[87] the number of different types of music represented in the above list is impressive, ranging from dances to an Italian madrigal and Church music.

Despite public reaction today to the crumhorn's appearance or to its sound when badly played, the crumhorn was far from being a joke. Its role in musical life was a limited but serious one, and a consort of crumhorns, like their keyboard equivalent the regal, was ideally suited to solemn slow-moving music such as Schein's pavan.

It was in Germany, Italy, and the Low Countries that the crumhorn and its reed-capped relatives seem to have been most popular. In spite of Henry VIII's collection of twenty-five crumhorns[88] there is no occasion when they are known to have been used, nor a single piece of English music which is associated with reed-cap instruments. A rare literary reference occurs in Sir William Leighton's *Teares or Lamentations of a Sorrowful Soule* (London 1613): 'With Crouncormes musicke laud the King of Kings with one accord.'[89] Curiously enough it was in France that crumhorns lingered on the longest. In 1650 'les cromornes et les trompettes marines' appear amongst the instruments of the *Grande Écurie du Roy:* several members of the Philidor family doubled on crumhorn and tromba marina (an unlikely combination if ever there was one) as well as oboe and fife and there is a surviving suite *pour les cromornes* by Degrignis (1660).[90] It is thought that the crumhorns of the *Grande Écurie* may have differed considerably from the renaissance type. Mersenne (1635) illustrated a thick sausage-like crumhorn with the finger-holes at the side and a curiously insecure looking reed-cap. A number of museums possess crude leather-covered instruments of this kind.[91]

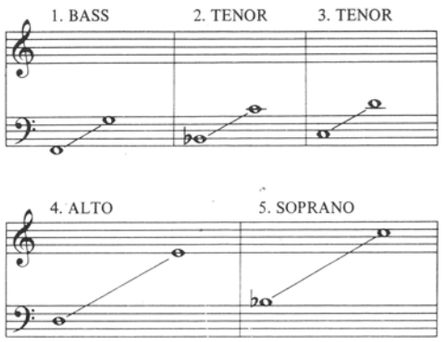
**The cornamuse**

'Corna Muse are straight like bassanelli. They are covered below, and around the bell have several little holes, from which the sound issues. In sound they are quite similar to crumhorns, but quieter, lovelier, and very soft. Thus they might justly be named still, soft crumhorns, much as *cornetti muti* could be called soft cornetts.'[92]

So writes Praetorius, giving us the clearest description that we have of this instrument. No cornamuse has survived, nor does Praetorius illustrate it, so we cannot be sure of its outward appearance. He states that the cornamuse had no keys[93] and his family sizes reveal in each case the limited range of a ninth, characteristic of reed-cap instruments.

The name *cornamuse* (derived from the medieval Latin *cornamusa*) is a confusing one since it most commonly means bagpipe, as in the French *cornemuse* today. When we find the name included amongst the instrumental ensembles heard at courtly entertainments it must be the reed-cap instrument rather than the bagpipe which is meant. The music at the banquet held in Munich to celebrate the marriage of Albert V of Bavaria to Renée of Lorraine in 1568 included a mixed consort of harpsichord, trombone, recorder, lute, *cornamusa*, mute cornett, viol, and *piffero*.[94] Anthony Baines[95] believes that in Italian usage

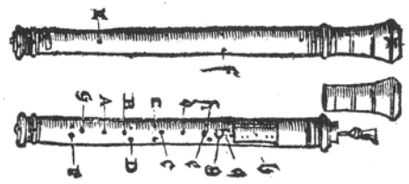
*cornamusa* actually meant crumhorn and not the softer, straight instrument described by Praetorius. Another ambiguous name crops up in the Munich account of 1568: there was a heterogeneous ensemble consisting of *dolzaina, cornamuse,* shawm, and mute cornett.[96] *Dolzaina* (from the Latin *dulcis,* sweet) takes us back to the confusion of douçaine/dulceuse/dulcian (see page 43).[97] No *dolzaina* has survived, nor is it ever depicted, nor unfortunately does Praetorius mention it. However, Zacconi (1592)[98] tells us that it had a compass of a ninth and with the addition of two keys could ascend by two further notes (these keys must have been very similar to the 'extra' keys fitted by most crumhorn makers today). To all intents and purposes the dolzaina must have been very similar to the cornamuse: a straight cylindrical-bore reed-cap instrument. Whatever the distinction between the two may have been we shall probably never know.



Cornamuse ranges from Praetorius' *Syntagma Musicum.*

### The kortholt

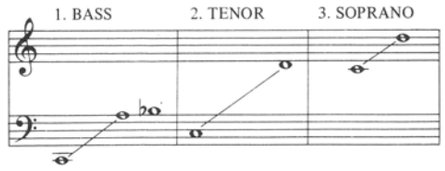
The reed-cap principle was applied to the cylindrical double-bore instruments too. The kortholt (literally *kurz Holz,* short wood) is basically a courtaut or sordun provided with a reed-cap. Praetorius[99] admits to being rather short on information about it and he was puzzled by the disparity in pitch between the kortholt that he had seen and the equivalent size of sordun. He does not give a complete table of ranges but he does illustrate the instrument, calling it *Kortholt oder Kurzpfeiff.* The illustration shows a bass size of kortholt: for the top two notes keys are provided, no doubt similar to those on the dolzaina mentioned by Zacconi. Modern makers have assumed that a complete *stimmwerk* must have existed and added three other sizes to produce a complete 4-part consort.



Kortholt from Praetorius' *Syntagma Musicum.*

### The doppione[100]

The double-bore reed-cap instruments certainly occupy one of the most murky corners of renaissance instrument history. Even the indefatigable Praetorius confesses of the *doppione* that 'In spite of my efforts I have not been able to examine such an instrument'[101] and concludes vaguely that it must be like the kortholt, sordun, or cornamuse. However, he gives the following ranges, which correspond with those given by Zacconi (1592), who Praetorius tells us is his source of information. Cerone (1613) copies Zacconi also, but uses the name *doblados.*[102]



Doppione ranges from Praetorius' *Syntagma Musicum.*

In one respect we are more fortunate than Praetorius, since two doppioni have survived, albeit in rather worm-eaten condition, for our examination. They are now in the collection of the Teatro Filarmonico of Verona, which also includes recorders, flutes, crumhorns, and cornetts. From a recent exhaustive survey[103] a number of rather curious facts have emerged.

1. On both doppioni there was originally a reed-cap although this is now missing.
2. There is provision for *two* crooks or staples at the top of each instrument, and consequently there must have been *two* reeds for each instrument.
3. The doppioni have parallel *conical* bores.
4. Both bores expand towards the bottom end of the instrument: in other words instead of one continuously expanding bore (as on the curtal) there are two expanding bores which meet in a common U-joint.
5. Each bore has the basic set of seven woodwind finger-holes but one set is placed much lower down the instrument than the other.

The authors of the survey mentioned above (Rainer Weber and J. H. van der Meer) conclude that the two bores of the doppioni were *alternatives,* designed to be played separately. Only one reed at a time was employed, of course, the player selecting the appropriate one for the bore which he was to use. Thus the doppione was a two-in-one instrument rather as, on a grander scale, the early two-manual harpsichord was, with its lower keyboard tuned a fourth below the upper one. Each doppione offered a pair of consort sizes: (1) soprano/alto, (2) alto/tenor, (3) tenor/bass, (4) bass/great bass.

The Verona instruments correspond to 2 and 3, whilst the instruments mentioned by Zacconi, Cerone, and Praetorius correspond to 1, 3, and 4. The ranges given by these writers can be seen to be only partially correct: for the two smaller doppioni only half the instrument was taken into account, giving the characteristically limited range of a ninth; for the largest the combined range of both bores is given. Rainer Weber and J. H. van der Meer also conclude that the Verona doppioni started life as reed-cap instruments, but were later blown directly in the manner of a sordun or courtaut.

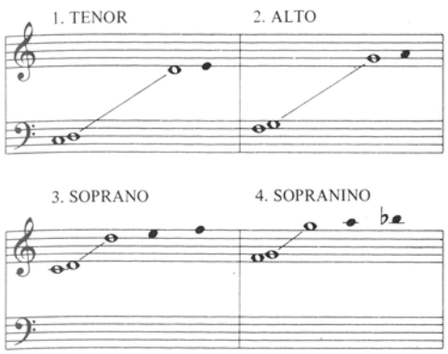
### Rauschpfeife and schreierpfeife

All the reed-cap instruments dealt with so far belong to the 'bas' or soft class; even the crumhorn, more strongly voiced than the rest, lacks the carrying power necessary for out-of-doors. *Rauschpfeifen* and *schreierpfeifen,* however, are reed-cap shawms and their place is with the 'haut' instruments of the outdoor band.



Modern rauschpfeife ranges.

According to Marcuse[104] the name *Rauschpfeife* is derived from the old German *Rusch* (=rush) and means simply *reed-pipe*. Confusingly both Virdung and Agricola use the name *Russpfeife* to describe a short wide-bore recorder with four finger-holes (see below, pp 57–8). The origin of the name *Schreierpfeife* (Italian *schryari*) is unclear: perhaps it had something to do with the instrument's 'screaming' tone quality (*schreien*=to cry). Of the two, rauschpfeifen seem to have been more common: there is a grand woodcut showing five of them being played on horseback in the *Triumph of Maximilian I* and 5- and 6-part consorts of rauschpfeifen survive in collections in Berlin and Prague respectively.[105] Together these instruments cover the soprano to bass registers: the smallest instrument (in Berlin) is a little over a foot long and is equivalent to the *kleindiscant* shawm, the largest (in Prague) is over four feet long and is suitable for bass parts. The omission of rauschpfeifen from the *Syntagma Musicum* is rather curious, although Praetorius does illustrate a type of reed-cap shawm which he calls a *Bassett Nicolo*. This is an alto instrument in F fitted with extension keys and, apart from the reed cap, is identical in design to the other large shawms shown by Praetorius. He gives the compass as a basic 9-note range from f–g′ plus three extension keys going down to c.

As far as rauschpfeifen are concerned, the contemporary nomenclature for the various sizes is not clear: modern makers produce the sizes shown above.

Because the rauschpfeife has an expanding conical bore like the shawm, it overblows at the octave and unlike other reed-cap instruments one or two useful extra notes are obtainable in the second octave. The larger sizes have a little-finger-key and fontanelle for the lowest note. A late French type of reed-cap shawm is described by Mersenne[106] under the name *hautbois de Poitou:* he gives three sizes, soprano, alto, and bass. The soprano is equivalent to the *chalumeau*, the chanter of the *cornemuse* (French bagpipe), and the same instrument could either be played separately with a reed-cap or as an integral part of the bagpipe. Mersenne shows the bass *hautbois de Poitou* with a doubled-back bore, like the curtal, though this type of instrument is not heard of elsewhere. In France an ensemble of *hautbois et musettes de Poitou* was still included in the royal band in the time of Lully, who used them to introduce the finale of his music to *Le Bourgeois Gentilhomme*.[107] Their folk descendants are still to be heard in Brittany today: the *bombarde* (small shawm) always plays in combination with the *biniou* (bagpipe).

The *Schreierpfeife* or *Schryari* is rather more of a mystery since no specimens are extant. In 1541 the Nuremberg trumpet maker Georg Neuschel offered Duke Albrecht of Prussia some *Schreyende pfeiffen* he had received from Lyons and Venice which he said were far louder than shawms.[108] Several German inventories include a consort of *Schreierpfeifen* and Praetorius gives the following sizes:

Schryari ranges from Praetorius' *Syntagma Musicum*. He omits to indicate the upper limit of the alto schryari.

He tells us that the instrument is non-overblowing with a 'strong and fresh' tone[109] and his illustrations reveal several interesting features. The larger sizes have *upward* extension keys operated by the index finger, like those shown on the kortholt: in his table Praetorius gives the range of two types of tenor schryari, one with the extra keys and one without. The smallest size is an alto on which the bottom end of the instrument is covered, but provided, Praetorius tells us,[110] with numerous vent holes. The tenor and bass are open-ended with a small flared bell. The most surprising feature however is that the exterior of the schryari is conical, but tapering *away* from the reed cap. Whether this indicates that the bore is contracting instead of expanding it is impossible to say, but if the schryari did have a contracting bore it would have been an extremely unusual instrument. Curt Sachs has suggested that it may have been of oriental provenance.[111]

In conclusion it may be helpful to summarize the different categories of renaissance reed instruments by means of a table. The phagotum and *Tartöld* have not been included since they may be regarded as 'sports' rather than established instrumental types.

**The bagpipe**

A word may be added at this point about the renaissance development of the bagpipe. Although not a reed-cap instrument in the sense described above, it does involve a similar separation of the reed from the mouth, and to an extent all reed-cap instruments can be regarded as derivatives of the bagpipe. Whilst the crumhorn, rauschpfeife, and their relatives are essentially ensemble instruments, the bagpipe remained an ideal solo instrument. Although two or three rustic pipers probably improvised simple part-music as they still do in Southern Italy or Spain today, and regiments of military pipers played in thrilling unison, the bagpipe's limitations[112] clearly prevented it from any involvement in the mainstream of renaissance music. There was still some association with the court: Henry VIII's Inventory[113] includes five bagpipes 'with pipes of Ivorie' and as late as Elizabeth I's reign a solitary bagpiper, Richard Woodwarde, is listed amongst the King's Music.[114] But during the Renaissance the emphasis gradually shifted from court to country, as the Elizabethan actor Robert Armin makes clear in *A Nest of Ninnies*. 'At Christmas time, when great logs furnish the hall fire . . . and indeed all revelling is regarded . . . amongst all the pleasures provided, a noise of minstrels and a Lincolnshire bagpipe was prepared; the minstrels for the great chamber, the bagpipe for the hall; the minstrels to serve up the knight's meat and the bagpipe for the common dancing.'[115] As an instrument of rustic and popular merrymaking the bagpipe has been immortalized in the paintings of Pieter Breughel and his contemporaries.

During the sixteenth century the bagpipe started to form its special ties with Scotland and Ireland. Most Scottish towns employed a town piper and drummer to perform much the same function as the English 'waits'. Yet it appears that in the Scotland of those days the music of the pipes was not to everyone's taste, for in 1630 the town of Aberdeen decided to dispense with the services of its bagpiper. 'The Magistrates discharge the common piper of all going through the town at nycht, or in the morning, in tyme coming, with his pype – it being an incivill forme to be usit within sic a famous burghe, and being often found fault with, als weill by sundrie nichtbouris of the toune as by strangers.'[116]

Meanwhile the Irish had developed the great war-pipe or *píob mhór*. In his *Dialogo della musica antica e della moderna* (1581) Vincenzo Galilei says of the Irish and their *píob mhór*: 'To its sound, this unconquered, fierce and warlike people march their armies and encourage one another to feats of valour. With it also, they accompany their dead to the grave, making such mournful sounds as almost to force the bystander to weep.'[117] Small sets of 'indoor' bagpipes were popular during the Renaissance too, especially in France. Praetorius[118] describes a small French instrument which was bellows-blown: this was the ancestor of the eighteenth-century *musette* and the Northumbrian small-pipes and Uillean pipes of today. The size, construction, and tuning of renaissance bagpipes varied so enormously that no detailed analysis will be attempted here: readers are once more referred to the books by Anthony Baines and Francis Collinson.[119]

## The flutes

During the Renaissance the word 'flute' continued to be used as a generic term denoting both recorder and transverse flute and when it occurs on its own without some kind of qualification we cannot always be quite sure which instrument is meant. On the continent 'flute' was sometimes used specifically for the recorder: there is no ambiguity about the *flöte* of Praetorius (1619) and the *flauto* of Ganassi (1535). On other occasions there *is* a problem of identification: although both Praetorius[120] and Philibert Jambe de Fer[121] tell us that Italians called the recorder 'flauto', this would seem to be an over-simplification. The ritornello for three flutes from Peri's *Euridice*, 1600 ('Zinfonia con un Triflauto') could be either for transverse flutes or recorders.[122] The trouble was that the continental languages lacked an equivalent to the convenient English word 'recorder'. In England a regular distinction between the two instruments does seem to have been made during the sixteenth century and 'flutes' and 'recorders' are often mentioned side by side. According to the chronicler Holinshed, writing in 1510, King Henry VIII was

'excercising himself dailie in shooting, singing, dansing, wrestling, casting of the barre, plaieing at the recorders, flute, virginals . . .'[123]

Henry VIII's Inventory[124] includes over seventy 'flutes' and over seventy 'recorders' and the Lord Chamberlain's records of the *King's Musick* list seven recorder players and seven flute players for the funeral of Queen Elizabeth in 1603.[125] Yet by the time of the Restoration the transverse flute had dropped out of use altogether in England and Purcell and his contemporaries invariably referred to the treble recorder in F as a 'flute'. When did this change in nomenclature begin: It would be fascinating to know, if only to establish which instrument should be used in Thomas Morley's *First Book of Consort Lessons* (1599)[126] and other consort music[127] scored for the typically English 'broken consort'[128] of treble viol or violin, 'flute', bass viol, lute, cittern, and bandora. The celebrated picture of Sir Henry Unton's wedding shows a broken consort with a transverse flute, yet in the set of manuscript part-books containing a number of Morley's pieces (now in the Cambridge University Library) the flute part-book is labelled 'the recorder part'.[129] Furthermore Praetorius, who writes with admiration in his *Syntagma Musicum*, Volume III, about the novel and extraordinary effect of the English broken consort, twice mentions the use of 'eine Querflöit oder Blockflöit' (transverse flute *or* recorder).[130] Perhaps as Sydney Beck has concluded[131] the flute and recorder were to some extent alternatives in the broken consort, just as the treble viol and violin were. But as far as English nomenclature is concerned, although 'flute' *generally* referred to the transverse instrument during the sixteenth century it cannot be established that it *always* did so.

On the continent a variety of names developed in order to distinguish clearly between flute and recorder. Back in medieval times the different playing positions of the two instruments had provided a means of distinction (*flaustes traversaines* and *flaustes dont droit joues quand tu flaustes*[132]): hence the use of *traverso* or *traversa* (Italian) and *Zwerchpfeife*, *Querflöte*, or *Querpfeife* (German, cross flute) for the transverse flute and *flauto dritto* (Italian, straight flute) for the recorder. Another distinction was offered by the supposed country of origin. As mentioned in chapter 1, the transverse flute was especially cultivated in Germany in medieval times and became known as the *flûte d'Allemaigne*[133] during the Renaissance. Later the recorder became known as the *flûte d'Angleterre* because of its popularity in this country. Another distinguishing feature was the number of finger-holes. The transverse flute was occasionally known as the *flûte à six trous* whilst the recorder was regularly called *flûte à neuf trous*: if the arithmetic sounds suspect it is because of the alternative holes provided for the little finger (*ie* 1 thumb-hole + 7 finger-holes + 1 alternative little-finger-hole = 9). The transverse flute was also sometimes called *fiffaro* or *fifre*, though the fife or *fistula militaris* was in fact a separate instrument (see below). The recorder was also called *Blockflöte or Plockflöte* after its 'block' or fipple and *flûte douce* because of its 'dolce' tone quality. Finally, mention should be made of the German name *Schwegel*, shinbone: it most commonly meant the three-holed tabor pipe, but unfortunately it was also used for the transverse flute and in the Austrian Alps for the recorder as well.[134]

It is hardly surprising to find some confusion between the recorder and flute at this stage in history, since the two instruments possessed a similar sound, technique, and function and their careers overlapped in many ways. The most important similarity is the way in which flutes and recorders normally operate at four-foot pitch, an octave higher than normal. The 'bass' flute or 'bass' recorder for example is in reality an alto instrument although it supplies the bass to the rest of the consort. Flutes and recorders maintained their four-foot role when playing in a mixed ensemble, often playing their parts an octave higher than written. Praetorius comments on this practice and on the fact that it is difficult to tell at what pitch a recorder or flute is playing, since they tend to sound an octave *lower* than is actually the case. Speaking of the tenor instrument (lowest note c′ or d′) he says: 'This recorder, and the cross flute in this register as well, may not only be used as a descant instrument . . . but also as a tenor, an octave lower. Various musicians believe that this type of recorder and cross flute actually is a true tenor instrument in sound and that its lowest tones – the C or D in the tenor register – produce a low pitch in the organ-maker's measure [Praetorius means c or d]. I too, was actually of the opinion for a time, for with the ear it is quite difficult to perceive the true pitch.'[135]

Although Praetorius does not mention the Morley *Consort Lessons* in this connection, it seems likely that the 'flute' part should sound an octave higher than written, whichever instrument plays it. As it stands the part lies uncomfortably low for either bass flute or recorder and in practice often just gets lost. The use of a tenor flute or recorder not only solves the balance problem but offers a much greater range of expression and dynamics as well. Altogether the Morley *Consort Lessons* and the other surviving broken consort music provide the recorder/flute player with a considerable challenge to his technique and musicianship. No other renaissance woodwind instrument can lay claim to a regular partnership with the most aristocratic and refined instruments of the day or a part share in some of the most exquisite chamber music of the time.

Besides the *Consort Lessons*, flutes and recorders were associated in a number of other sixteenth-century publications. In a songbook published by Arnt von Aich in about 1518 the title-page offers alternative methods of instrumental performance: '. . . lustick zu syngen. Auch etlich zu fleiten, schweglen, und anderen Musicalisch Instrumenten artlichen zu gebrauchen.'[136] (joyful for singing; some are also suitable for recorders, flutes, and similar musical instruments).[137]

Unfortunately Arnt von Aich does not tell us *which* pieces are most suitable. The Parisian publisher Pierre Attaingnant, however, who ran one of the most successful publishing businesses of the time, was more specific. In two chanson collections published in 1533[138] and evidently aimed at capitalizing on some kind of vogue for consorts of flutes and recorders, Attaingnant carefully marked up all the pieces which are most suitable for either instrument. On the title page he explains that

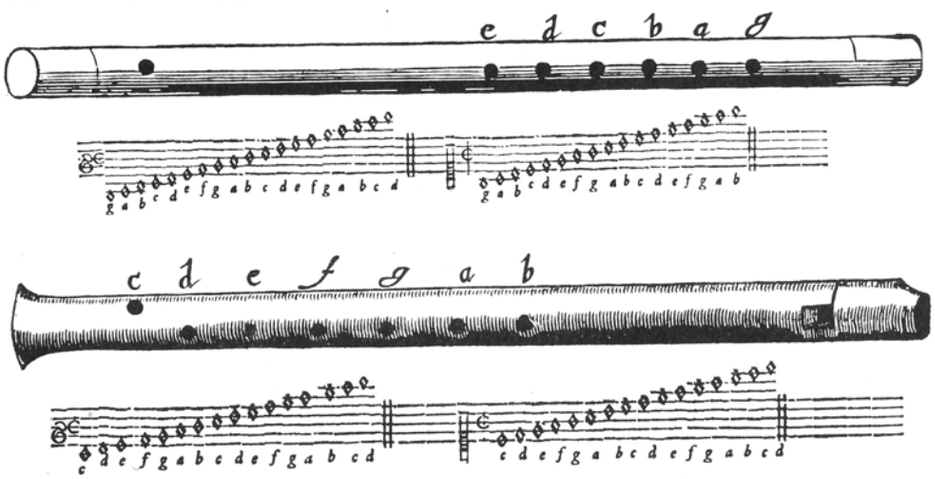
Title page of the second of Attaingnant's two chanson collections of 1533.



Flute and recorder with their ranges, from van Eyck's *Der Fluyten Lust-hof,* 1646.

the chansons which are 'les plus convenables a la fleuste d'allemant' (transverse flute) are marked with the letter *a*, those suitable for 'la fleuste a neuf trous' with the letter *b* and those suitable for both with *ab*. Although the reasons for Attaingnant's choice are not always clear, his selection of chansons provides some fascinating hints about the relative qualities of recorders and flutes.[139] In particular the flutes seem to be able to cope with a wider range than the recorders. Both instruments make a tantalizingly brief appearance in the score of Monteverdi's Vespers of 1610.[140] In the *Quia respexit* section of the *Magnificat* there are obbligati lasting only a few bars first for two *fifari* and then two *flauti*.[141] As late as 1646 both flute and recorder crop up together in the preparatory instructions of *Der Fluyten Lust-hof*[142] by Jacob van Eyck. Whilst the *Dwars-fluit* (transverse flute) is credited with a two-and-a-half-octave range, the *Hand-fluit* (recorder) has a compass of two octaves and one note. This disparity in range is confirmed by other writers including Agricola (1528 and 1545) and Philibert Jambe de Fer (1556): the latter emphasizes the gentleness of breath pressure required for the recorder.[143] In other ways the technique of flutes and recorders seems to have been generally similar. Different types of tonguing were called for, double-tonguing being needed for very fast divisions; Agricola even mentions a kind of flutter-tonguing.[144] He also makes it clear that even in the fastest passage every note should be tongued. The existence of brilliant divisions such as those of van Eyck, together with the examples given in various instruction books, suggest that sixteenth-century flute and recorder players possessed a very accomplished technique indeed. However when recorders or flutes played together in consort there were evidently tuning problems then as now. Round about 1530 a new metaphor was adopted into the French language: *accordez vos flûtes* meaning 'agree amongst yourselves'.[145]

Altogether more information is forthcoming about the flute and recorder than about the majority of renaissance woodwind instruments. For a thorough summary of the evidence about the renaissance flute, the reader should consult the article on the subject by Joscelyn Godwin[146] together with that by Bernard Thomas[147] investigating the practical application of the evidence. It is to be hoped that their work encourages a greater understanding and appreciation of the renaissance flute, sadly neglected today in comparison to the renaissance recorder. During the sixteenth century flutes were tremendously popular: they were widely illustrated and often form the largest item in inventories, as in that of the Stuttgart Hofkapelle in 1589 where there was a staggering total of 220 flutes compared to 113 cornetts, 48 recorders, and 39 viols.[148]

### The transverse flute

The renaissance flute has a cylindrical bore with six finger-holes and a very small round mouth-hole which demands a rather different embouchure from the baroque or modern flute. According to Mersenne 'it is a great deal more difficult to make this flute speak than the others which are blown at the end [*ie* recorders] since everyone can use the latter but few know how to sound the former because of the difficulty found in placing the lips as required on the first hole'.[149] Besides the basic sound production, the renaissance flute is a tricky instrument to handle in other respects: a number of notes are naturally out of tune and need 'helping' by turning the instrument in order to alter the angle of embouchure. Curiously enough this essential aspect of technique does not appear to be mentioned by any renaissance writer.[150]

According to most of the sources, flutes were made in three principal sizes separated by a fifth: alto in A, tenor in D, and bass in G. The smaller sizes were made in one piece, and the bass was sometimes jointed, as shown by Praetorius. A study of surviving instruments,[151] however, suggests that many were in fact pitched a tone lower than this, *ie* alto in G, tenor in C, and bass in F. If this were the case a great deal more ensemble music would suit a consort of flutes than is the case with the A-D-G tuning. Bass parts do tend to go down to F, and the nature of renaissance music makes B♭ and E♭ fairly common notes (very uncomfortable on flutes pitched in 'sharp' keys). This hypothesis receives some support from Volume III of the *Syntagma Musicum,* where the suggestions which Praetorius makes about music which is suitable for flutes rather contradict his illustrations of flutes in Volume II with their A-D-G tuning.[152]

In spite of being known as a *German* instrument, the idea of a flute consort caught on in France before it did in Germany. Writing about the *fleuste d'Allemand* in his memoirs, the Duc de la Vieilleville says: '. . . les François s'en aydent mieulx et plus musicalement que toute autre nation, et jamais en Allemaigne n'en fut joué à quatre parties, comme il se fait ordinairement en France.'[153] (The French make better and more musical use of it than any other nation, and in Germany it is never played in four parts as is the custom in France.)

The earliest account of the compass of the flute comes in the first edition of Agricola's *Musica instrumentalis deudtsch,* published in 1528, where each flute is given an astonishing three-octave range. In later editions Agricola somewhat modified his ideas, perhaps, as Joscelyn Godwin suggests, as a result of having experienced the highest notes as described by Philibert Jambe de Fer '. . . ilz sont fort cruz, et rudes, pour la vehemence du vent qui y est necessaire, et pour ceste cause sont peu usitez . . l'experience vous en rendra plus certain.'[154] (Because of the force of breath pressure required, they are very crude and harsh and for

this reason are little used . . . actually hearing them would make you positive of this.)

Most theorists agree on a comfortable two-octave compass for the flute: the range given by Praetorius may be taken as standard for the period. Clearly the tenor flute with the possibility of extra 'falsetto' notes was the most useful size.

Of the three sizes, the bass is the hardest to handle because of its length. However lightly made, it becomes tiring to hold and most basses require a very wide stretch of the fingers, far greater than on the equivalent size of recorder where the holes can be bored at more of an angle, and so brought within easier reach of each hand. A number of pictures show a diagonal position which is certainly more comfortable than trying to hold the bass flute horizontally. This involves a rather different style of embouchure too: blowing partly *down* the instrument instead of *across* it, and in his *Traité des Instruments de Musique* (*c*.1640) Pierre Trichet appears to mean something of the kind when he says that the bass flute is played 'par derrière'.[155]

Apart from what has already been mentioned, there is little definite information about the use of flutes in sixteenth-century music. In the courtly *intermedii* there seems to have been a symbolic association with seascapes.[156] In the Medici wedding celebrations of 1539, Francesco Corteccia's music for the second intermedio featured three sea monsters playing flutes which were disguised as a fish's backbone, a sea snail, and a sea marsh cane.[157] In Count Bardi's intermedii to *L'Amico Fido* of 1585 there were flutes in the sea scene, although the gods descended to the sound of flutes as well.[158]

Some mention should be made of the military branch of the flute family, which goes back to medieval times. During the Renaissance the fife was variously known as *fistula militaris*, *Schweizerpfeife* (Swiss pipe), or *Feldpfeife* (field pipe). The latter names came from the instrument's use in the Swiss infantry fife-and-drum corps.[159] The main difference between flute and fife lay in the length and bore. As Arbeau succinctly puts it in his *Orchésographie* (1588): 'What we call the fife is a little transverse flute with six holes, which the Germans and the Swiss use, and as its bore is very narrow, only the width of a pistol bullet, it gives a shrill sound.'[160]

Praetorius gives two sizes (*see overleaf*).

Fifes occupy an important place in the *Triumph of Maximilian I* (1512). Three fifers are shown on horseback with their fife cases at their sides. They are led by one Anthony 'the fifer' who carries the following verse inscription:

I, Anthony of Dornstätt, have played my fife
For Maximilian, great in strife,
In many lands and on countless journeys,
In battles fierce and knightly tourneys.[161]

**The recorder**

'Govern these ventages with your fingers and thumb, give it breath with your mouth, and it will discourse most eloquent music. Look you, these are the stops.'[162]

Hamlet's remarks to Rosencrantz and Guildenstern read like an extract from some contemporary manual of recorder instruction. And uniquely among wind instruments, the recorder did have its own published tutor during the Renaissance: the *Opera Intitulata Fontegara*[163] by Sylvestro Ganassi, issued in Venice in 1535. It is appropriate that the city of Venice, which produced so many fine recorders, should also have produced the first recorder tutor. Ganassi (born in 1492) was a court musician to the Doge of Venice and an instrumentalist at the basilica of St Mark's. He played the viol as well as the recorder and produced a book of instruction for the former instrument too: the *Regola Rubertina* (1542/3). Judging by the *Fontegara*, recorder playing had achieved a high degree of technical accomplishment by Ganassi's time. The care taken to explain different methods of articulation, alternative fingerings, and the complex art of improvised ornamentation is impressive. Even more so is the extent of Ganassi's fingering chart which gives the recorder a compass of two octaves and a sixth: a fifth higher than the standard range of the baroque recorder, *after* Hotteterre's improvements. Players (or instruments) capable of such a wide range must have been the exception rather than the rule during the sixteenth century.

Most of the renaissance writers on instruments give us valuable information about the recorder: for a full survey the reader should consult Edgar Hunt's *The Recorder and its Music*.[164] Virdung devotes the last eighteen pages of his *Musica getutscht* to the instrument. He describes three sizes: bass in F, tenor in C, and alto in G and illustrates a typical four-part recorder consort with two tenors. Virdung calls his alto *discant*, showing that this was the standard top-line instrument of the consort, not the soprano which we call *descant* today. He gives each instrument a range of just under two octaves and shows how to arrange suitable music for the consort. The piece he selects is a hymn: *O Haylige, onbeflecte, zart*.

During the century after Virdung's publication the recorder family expanded. Praetorius illustrates no less than eight sizes, from the tiny *exilent* in G (what we would today call a sopranino) down to the great bass in F.

'A complete set such as this can be procured in Venice for about eighty thaler' Praetorius tells us.[165] If only that were still the case! These days the largest sizes are very expensive to make and comparatively few modern reproductions have been produced. The great bass must always have been an awkward instrument to manage: even though the finger-holes are brought as close to the reach of each hand as possible (by boring the outer holes of each group of three at an angle) the stretch required is considerable. With a large windway which responds to gentle breath pressure, separated from the player's mouth by a long crook, the great bass also demands a rather special type of articulation.

Praetorius explains that the wide range of recorder sizes offered a number of separate consorts within the family, which were made up, like Virdung's consort, of three adjacent instruments.[166] You could have an ensemble of soprano, alto, and tenor, for example, playing their music an octave higher than written, at 4-foot pitch, or the deliciously mellow combination of bass, quart-bass, and great bass, which operated at 'normal' 8-foot pitch. The latter is what Mersenne called the *grand jeu* (a phrase borrowed from organ terminology) and he describes the effect of the full consort: 'Now these flutes form the small group, while those which will follow after form the large group, but they can all be tuned [*ie* played] together, as are the large and small stops of the organ.'[167]

Praetorius preferred the deeper sounding instruments. In Volume III of his *Syntagma Musicum* he says: 'When a canzona, motet, or *concert per choros* is to be played on recorders alone, without other instruments, it is very good and fitting to use the whole range of recorders, especially the five largest kinds, for the small ones are much too loud and piercing. This gives a very soft, sweet, and pleasant harmony, especially in rooms and chambers.'[168] He goes on to say that in a church the large recorders cannot be heard very well and recommends using a curtal as the bass when combining recorders with voices.[169]

Surprising as it may seem, even larger sizes of recorder were built than Praetorius' great bass in F. Having reached the limit of what was practicable with the placing of finger-holes, makers resorted to extension keys after the shawm pattern. Mersenne illustrates such an instrument and the collection of the Vleeshuis, Antwerp,[170] preserves a great bass with three extension keys descending to low C.[171]

Besides the joint flute/recorder repertoire, there are a number of interesting sixteenth-century references to the use of the recorder alone. Guillaume Vorsterman's *Livre Plaisant et tres utile*, published in Antwerp in 1529, includes the well-known chanson by Jacobus Barbireau (d. 1491) *Een Vrolic Wesen* in what is almost certainly an arrangement for recorder and lute.[172] A copy of a song book published by Georg Forster in 1539 has been preserved with certain pieces marked up by hand for the *flöt*.[173] Recorders were regularly used in church, not only in Germany but in Spain too. The accounts of Seville Cathedral record several purchases of recorders and the instruments were employed to give musical variety to the services. In a directive of 11 July 1586: 'At greater feasts there shall always be a verse played on recorders. At Salves, one of the three verses that are played shall be on shawms, one on cornetts and the other on recorders; because always hearing the same instrument annoys the listener.'[174] In 1549 a *caxa de flautas grandes* was bought for Guatemala Cathedral[175] – surely as Lawrence Wright suggests[176] the earliest known evidence of recorder playing in the New World.

As far as the other whistle instruments of the Renaissance are concerned, the most important was the tabor pipe which regularly crops up in the inventories. Like the bagpipe it retained its medieval function as a solo instrument and was not used in consort. The tabor pipe has already been dealt with in chapter I together with the six-holed pipe, gemshorn, and flageolet. Three other types should be mentioned briefly. Virdung illustrates a four-holed *Russpfeif* which looks as if it is made from bone. Agricola devotes a chapter to a small four-holed recorder on which one stops the end as well as the holes and Praetorius illustrates a similar instrument. Praetorius also illustrates *Dolzflöten:* whistle instruments made to look like transverse flutes, similar to the folk instruments still found in India and Pakistan today. Antony Baines suggests that they may correspond with the *Zwerchflöten* (as opposed to *Zwerchpfeifen*) found in some inventories.[177]

Despite the considerable refinements and improvements in the construction of woodwind instruments which took place during the Renaissance, it is instructive to remember that, on paper at least, much more novel and far-reaching developments were proposed. By way of a postscript to this chapter, the reader is referred to the many sketches for musical instruments and musical machines in the notebooks of Leonardo da Vinci.[178] Eight of the sketches show the application of a complete system of keywork to wind instruments. Although the drawings are in the nature of preliminary jottings rather than fully worked

out designs, Leonardo clearly envisaged the possibility of a keyed trumpet and a keyed *zufolo* or pipe: the instruments are equipped with something like a miniature keyboard and mechanical stopping devices. It was not until 1840 with the work of Theobald Boehm that a complete keywork for wind instruments, replacing the principle of finger-stopping, was introduced into instrumental construction. As Emanuel Winternitz has pointed out,[179] the sketches of Leonardo anticipate Boehm's epochal invention by three centuries and a half.

From the tiny amount of solo organ music which has survived from before the fifteenth century we cannot be sure just how extensively the medieval organ may have been used as a solo instrument. But its main functions must have been to give support to the voices in church and to play a part in the concerted vocal and instrumental music of the court. During the Renaissance, however, the art of the keyboard became predominantly a solo art. From the fifteenth century onwards first the organ and subsequently the harpsichord and virginals acquired a vast solo repertory of their own. As with the solo lute repertory, the range of music is enormous. Composers took delight in making keyboard settings of every type of vocal piece: motets, mass movements, chansons, frottole, and madrigals. They seized on the new dance forms of the Renaissance – the pavan, galliard, alman, and coranto – and the new instrumental forms – the canzona, fantasia, and *in nomine*. And they developed new idiomatic keyboard types such as the prelude, the toccata, and the variation. Playing keyboard instruments became popular with amateurs as well as professionals, and amongst the middle classes as well as at court. As Castiglione remarks in his book *Il Cortegiano* (1528): 'all the keyboard instruments are very harmonious because they give the harmonies with great perfection, and many things can be performed on them which fill the spirit with melodious sweetness'.[1]

The number of publications from the second half of the sixteenth century[2] shows that printing keyboard music was good business, though the enthusiast often built up his own manuscript collections of favourite pieces. That of the organist Thomas Mulliner[3] gives us a fascinating cross-section of music from mid-sixteenth-century England, and a number of such collections were made for the harpsichord or virginals, the most famous being *The Fitzwilliam Virginal Book*.[4]

The Renaissance produced a number of outstanding composers whose output was principally or even exclusively of keyboard music and who were themselves famous performers. The German organist Paul Hofhaimer (1459–1537) earned high favour with the Holy Roman Emperor Maximilian I. He frequently accompanied the emperor on his journeys and is depicted playing a positive organ in the *Triumph of Maximilian I*.[5] The Spanish composer Antonio de Cabezón (1510–66) became organist and clavichordist to the Emperor Charles V at the age of eighteen. He continued in the royal service under Philip II, with whom he travelled to Italy, Flanders, and England. The epitaph on Cabezón's tombstone described him as 'the first organist of his time, whose fame fills the world'.[6] Amongst the English virginalists, John Bull (1562–1628) became celebrated on the continent as a great virtuoso. He toured through France, Germany, and the Netherlands and ended his days as organist at Antwerp Cathedral. Bull became a close friend of Jan Pieterszoon Sweelinck (1562–1621) whose organ recitals at the Oude Kerk in Amsterdam attracted pupils and admirers from all over Europe. He was known as the 'Glory of Amsterdam', and the merchants of the city showed their appreciation by making up a purse for Sweelinck in 1604, and subsequently presenting him with a *clavicembalo* and a finely woven cloth to cover it.[7] The organists' jobs which were most highly thought of – and the best paid – during the sixteenth century were those of first and second organist at the basilica of St Mark's, Venice. A succession of distinguished composers occupied the posts including Andrea Gabrieli (1510?–86) and Claudio Merulo (1533–1604). St Mark's was the first church to have two large organs built[8] and their existence, together with the basic design

of the building with its various galleries for performers, helped to develop the antiphonal style of *cori spezzati* for which Venice became famous at the end of the sixteenth century.

Such details as these serve as a reminder of the different schools of keyboard playing and composition which developed during the Renaissance. With them grew up different schools of making too, each with their own very distinctive traits. There could scarcely be a greater contrast between the English organs of the sixteenth century, with only one manual, no pedals, and a few flute stops, and those of the North German School with three manuals, a pedalboard, and a host of colourful mixtures, flutes, and reeds to choose from. There is an equally marked difference between the straightforward harpsichords and spinets of the early Italian makers and the rather grander harpsichords and virginals of the Flemish school. All in all the amount of information available about early keyboard music and the instruments, makers, and players is encyclopedic. Beyond the brief survey which follows readers are referred to the works listed in the footnotes.

One general point may be made about the use of keyboard instruments in *ensemble* music during the sixteenth century. Artists regularly depict them being played in consort and other sources illustrate the sort of company they kept. In one of the *intermedii* of 1565 celebrating the wedding of Francesco de Medici to Joanna of Austria, the instrumental music played before the Prologue at the opening of Heaven was scored for: four double harpsichords (*gravicembali doppi*), four viols, two trombones, two tenor recorders, one mute cornett, one transverse flute, and two lutes.[9] At the banquet held in 1568 in Munich for the wedding of Albert V of Bavaria a *regale dolce* (soft regal) played with six *viole da brazzo*, a cornett, and five trombones, whilst a harpsichord accompanied singers in one piece and in another joined a mixed ensemble of trombone, recorder, lute, *cornamusa*, mute cornett, viol, and *piffero*.[10] In such ensembles the role of the keyboard must have been primarily a chordal one, and although we have no precise information about how players may have 'realized' their part, the style may to some extent have anticipated the continuo of the early baroque period. With the advent of opera in Italy and the new musical habits of the seventeenth century, keyboard instruments, along with the harp, lute, and chitarrone, became indispensable to music of all kinds because of the harmonic support which they could provide.

Some mention should be made of the system of tuning employed on keyboard instruments during the renaissance and early baroque periods. As early as 1511 Arnolt Schlick gives a clear account of how an organ should be tuned and anticipates the system of 'mean tone' temperament.[11] Unlike the systems of equal temperament in use on keyboard instruments today, mean-tone tuning involves a kind of juggling with the relationship between semitones which favours the most commonly used keys and intervals at the expense of other less common ones. Schlick directed that ascending fifths should be made flat so as to accommodate the thirds, particularly: F–A, G–B♮, and C–E. He describes the interval from G♯ to E♭ as the 'wolf' and recommends the player to avoid using C♯ or A♭ as keynotes at all.[12] Mean-tone tuning is an uncompromising system but when properly understood it can give a new depth to early keyboard music. Its fallibilities worried the theorists, however. In his *Istituzioni armoniche* published in Venice in 1558, Zarlino illustrates a harpsichord which solved all the problems by offering nineteen divisions to the octave. All the 'sharps' are split – so that there were alternatives for G♯ and A♭ for example – and extra keys were provided between E and F and B and C. Impractical as it sounds, this instrument was actually constructed and played on by Luzzasco Luzzaschi, organist to the Duke of Ferrara.[13] It still existed as late as 1770 when Charles Burney came across it in Florence on his travels. Praetorius describes a similar instrument which he says might 'justly be called an Instrumentum Perfectum – if not perfectissimum'[14] and a number of other experimental harpsichords were made along the same lines. But Praetorius makes clear that the fretted instruments of the day used a system of tempered tuning different from the keyboard instruments. 'The harpsichord, symphony, and the like . . . are rather incomplete and imperfect in that they do not afford chromatic notes such as can be produced on lutes and viols da gamba.'[14] It would be interesting to know if keyboard players of the sixteenth and seventeenth centuries adopted a different system of tuning when they played in an ensemble. In his *Discourse on Ancient Music and Good Singing* Count Giovanni de' Bardi emphasizes that there was a problem: 'And more than once I have felt like laughing when I saw musicians struggling to put a lute or viol into proper tune with a keyboard instrument . . . In your consort, then, you will as far as possible avoid combining lutes or viols with keyboard instruments.'[15]

### The renaissance organ

At the end of the Middle Ages the large church organ was still a fairly unwieldy instrument. As William Leslie Sumner says in his book *The Organ*: 'Large instruments built in fine cases were found in many parts of Europe in the fifteenth century. They were intractable to play, capable of sustaining only the crudest counterpoint and sometimes only single-line melodies played with mixtures containing repeated octaves and fifth sounding ranks . . . When the tone was mollified by the reverberation of a vast Gothic cathedral there can be no doubt that its powerful diapason chorus would have considerable emotional effect.'[16]

Nevertheless, it was during the later fifteenth century that several major improvements were made in organ construction. During this period there was an upsurge of interest in organ playing and composition in Germany, and amongst a number of collections[17] by far the largest and most important is the famous Buxheim Organ Book (*c.*1470).[18] This collection frequently demands an agile finger technique and on occasions pedal technique too, pedals being actually specified in a few pieces and implied in others.[19] The high standard of organ playing in Germany at this time is hardly surprising after the example of Conrad Paumann (*c.* 1415–73), the blind organist of Nuremberg. In about 1450 he entered the service of Duke Albrecht III at Munich and also served his successor Albrecht IV. Paumann's career was a thoroughly international one: in 1470 he visited the courts of Ferrara and Mantua and in the following year he played the organ at Regensburg for the Emperor Frederick III. A contemporary eulogy describes Paumann thus:

Meyster ob allen maystern:
Solt man durch kunst einen meister kron,
er trug wol auf von golt ein kron.
(Master above all masters:
If one crowns a master because of his art,
He would surely wear a crown of gold.)[20]

For the benefit of his pupils, Paumann wrote a textbook, the *Fundamentum organisandi* (1452), which is the *locus classicus* of fifteenth-century organ teaching. From the point of view of organ *building*, however, the most useful treatise of this period is the *Spiegel der Orgelmacher und*

Title page of Schlick's *Spiegel der Orgelmacher und Organisten* (1511), showing a single-manual organ with pedalboard.

*Organisten* by Arnolt Schlick, published in 1511.[11] This describes in great detail an organ with a compass of three octaves and a third, organized in three sections, each with its own series of separate stops. On the 'positive' there were four registers of flue stops including a mixture and a gemshorn. The 'manual', the main part of the instrument, with eleven registers, was composed of reeds and flue stops, including a *Zink, Regall,* and *Rauspfeiffen,* whilst the pedals' four registers featured a 16-foot flue stop (*Principaln* 16) as well as a *Trommettan oder basaun*. Schlick also gives useful information on how the various registers should be employed.

The changes which had taken place in the construction and design of organs by the beginning of the sixteenth century may be conveniently summarized as follows:
1. The keyboard had been thoroughly 'modernized' to make it as responsive to the touch as that of the smaller sizes of organ.
2. Instead of the permanent 'mixture' sound of the large medieval organ, the registration for each keyboard could be controlled by a series of stops, which worked in a similar way to the old slider mechanism.
3. As well as open and stopped 'flue' pipes operating on the whistle mouthpiece principle there were a variety of 'reed' pipes employing a single vibrating tongue (usually metal) and a resonator, either conical or cylindrical.
4. The different stops were used for contrast and many of them were designed to imitate the sound of contemporary instruments.
5. Couplers were used to join manual to manual or manual to pedals.

During the late Renaissance organ-building flourished as never before. There were improvements, experiments, and refinements, and different schools of makers sprang up all over Europe. By the beginning of the seventeenth century the organ had become, especially in North Germany, Flanders, and Spain, a truly sumptuous instrument with carefully balanced registers and a colourful variety of sound. The tone was always bright and clear, sometimes even harsh. Schlick repeatedly uses the words *scharf schneidend* to characterize the stops he describes.[22] Some stops were positively raucous, such as the *trompeta exterior* or *real* favoured by Spanish makers. The appearance of the renaissance organ was equally sumptuous. The organ cases were often richly decorated with gold, azure, and vermilion; the pipes themselves were often silvered or gilded.[23] One of the most magnificent renaissance organs to have survived more or less intact is that in the royal palace of Frederiksborg in Denmark built in 1612 by Esaias Compenius. All the pipes are made of wood, many of them inlaid with ivory and ebony, and they are encased in a richly ornamented cupboard of oak. The keyboards, including the pedalboard, are faced with ivory and ebony and the stops are of solid silver each in the shape of a human face. The quality of sound still achieves a matching perfection even after three hundred and fifty years. Praetorius mentions Compenius[24] in the large section of his *Syntagma Musicum* devoted to the organ and he includes the specification of the Frederiksborg instrument, commenting on its exclusive use of wooden pipes.[25]

The names of some of the stops illustrate the extent to which organ builders drew on the sounds of contemporary woodwind instruments for inspiration. This was particularly the case in Germany where such a variety of woodwind types flourished during the Renaissance. On the Frederiksborg instrument Compenius included: on the upper manual a 4-foot *Gemshorn* and a 16-foot *Rancket* (= rackett); on the lower manual a 2-foot *Gemshornlein* (= little gemshorn), a 4-foot *Blockpfeiffen* (= 'blockflute' or recorder), an 8-foot *Krumbhorn,* and a 4-foot *Regal*; and on the pedals an 8-foot *Gemshorn,* a 4-foot *Querflöten* (= flute), a 16-foot *Sordunen,* an 8-foot *Dolzian,* and a 4-foot *Regal*.[25] That we can still hear these sounds today is thrilling, not only because the organ itself is a masterpiece of organ building but because it provides us with a direct link with the live sounds of the Renaissance. The organ builders could not accurately reproduce the sounds of strings or brass instruments, but with the woodwind they must have been able to copy fairly exactly, even though their method of sound production may have differed from that used on the instrument itself (for example, the use of *single* tongues instead of *double* reeds). The Frederiksborg organ and others of its period provide evidence of the sharply defined attack and uncompromising tone colours which must have been characteristic of renaissance woodwind instruments. The renaissance organ even shared some of their shortcomings: large unstopped flue pipes, like big recorders, tend to be soft and unfocused, whilst the highest notes of the crumhorn stop tend to be rather feeble, just as soprano crumhorns often are.

Whilst it is in the larger instruments that the greatest achievements of the renaissance organ-builders are to be found, the smaller positive and portative types continued to be produced. By its very nature the portative was a very restricted instrument and it gradually dropped out of use during the sixteenth century. But the positive continued to thrive as an invaluable instrument in court, chamber, or church. On the continent it was often equipped with one or two of the new reed stops and after 1600 it became indispensable as a continuo instrument.

**The regal**

Besides being one of the new reed stops of the renaissance organ the regal had a long career as a separate instrument in its own right. As Praetorius pointed out, the use of the same name is confusing: 'I believe it would be better to name this instrument a regal-works and to call the organ regal stops by the term regal-pipes, in order better to distinguish the one from the other.'[26]

In essence the regal is a small portable reed organ. Praetorius mentions that it could have up to three ranks of reeds (4-foot, 8-foot, and 16-foot) but most regals had just one rank of 8-foot reeds.[27] The instrument has a characteristic incisive attack and penetrating tone: the word 'snarling' has often been applied to it but there is a rich resonance too, especially in the lower register, similar to that produced by a consort of crumhorns. The earliest mention of a reed organ is in 1460 when Heinrich Traxdorff of Nuremberg constructed an organ the sound of which resembled that of the shawm. Galpin inferred that the instrument was a regal[28] and his opinion seems to be generally accepted. On the earliest regals the reeds were apparently open but later acquired short resonators of brass or wood.[29] Judging by surviving specimens the regal was more common on the continent than it was in England: this seems likely in view of the English preference for flute stops on the larger organs. Nevertheless, the Inventory of Henry VIII's instruments[30] reveals an impressive collection of no less than twenty-two regals including such varieties as 'one faire instrument being Regalles and Virgynalles', 'a paire of double Regalles with twoo stoppes of pipes couered in purple vellat', and 'v. small single Regalles twoo of them being in Cases of Timbre'.

The descriptions 'single', 'double', and 'a pair of' were regularly applied to both the regal and to the virginals and the exact meaning of these terms remains elusive. Certain of the solutions which have been offered can be discounted. A 'double' or 'pair of' certainly did not signify a two-manual instrument since no such form of regal existed and a two-manual virginal was a comparative rarity. Nor is it likely that one instrument was regularly placed on top of another in order to make a 'double' or 'pair'. Such a practice was not unknown in the case of stringed keyboard instruments: Praetorius mentions that the spinet 'is generally placed on top of larger keyboard instruments'[31] presumably to provide the player with a contrast of timbre. But in the case of the regal the existence of the bellows makes the idea of placing another instrument on top of it impossible. The most likely explanation of 'single' and 'double' is that the words refer to the instrument's compass.[32] Just as 'single' and

Table organ built by the German maker Haase in 1684. There are two ranks of stopped flute pipes (4′ and 2′) and one regal (8′). (Collection of Noel Mander)

'double' curtal described different sizes of dulcian, so a 'single' virginals or regal would have possessed a limited downward compass, whilst a 'double' would have had the full range. As for 'a pair of' this most probably refers to the division of keyboard between two hands in much the same way that we use the expression 'a pair of gloves'. The word 'regal' itself (French *regale;* German *Regal;* Spanish *realejo*) may be derived from the Latin *rigabellum* or *regula*.[33] Confusingly the name was sometimes used to describe a positive organ with a regal stop, as in Henry VIII's Inventory.

Besides possibly being the birthplace of the regal, Nuremberg is also thought to have produced the compact form of the instrument known as the Bible or Book regal. This invention is ascribed to the Nuremberg organ builder Georg Voll who died in 1565.[34] The ingenious design allows the keyboard and resonators to be packed away inside the 'book', the covers of which form the bellows.

One aspect of the regal mentioned by several authorities is its unstable tuning. Pietro Cerone (1613)[35] says that it is the worst of all instruments in this respect, going out of tune from one hour to the next, and Praetorius (1619) explains at length how the regal is susceptible to changes of temperature:

'I know only too well how much difficulty is caused the organist or director of an ensemble when several regals are to be played together in churches or at court dinners – and especially when in winter a regal must be brought out of the coldness of the church into a warm dining room. It is indeed true that metal pipes are forced down in pitch to such an extent by the cold of winter that they sink by half a semitone, if not more.'[36]

After observing that all organs – and wind instruments in general – fluctuate in a similar way ('and when the stoves are going these instruments become even sharper') Praetorius concludes stoically: 'Since up to now, no one has been able to establish the true cause for such variation and change, this must be taken for one of the extraordinary works of God.'[37]

In spite of this disadvantage, regals continued to be made throughout the seventeenth and eighteenth centuries (in England a tuner of 'His Majesty's regals' was still receiving a salary as late as 1779[38]). As a stop on the large organ the regal continues in use to the present day, though, as has happened with so many other organ stops, it has lost much of the reedy clangour with which the renaissance makers endowed it. Its highly individual tone colour prompted Monteverdi to use the regal with a consort of trombones in order to create the sinister atmosphere of the Underworld in Act III of his opera *Orfeo* (1607).

**The harpsichord**

The development of the harpsichord during the fifteenth century introduced a quite new type of stringed keyboard instrument employing a mechanical *plucking* action. The harpsichord is essentially a mechanized psaltery and the same method of sound production is used on the virginals and spinet. Each key on the keyboard operates a mechanical device known as the 'jack', which is equipped with a small plectrum (made of leather or quill) attached to a pivoted tongue. When a player presses down a key on the keyboard the jack rises and the plectrum plucks the string. When the key is released the jack descends and through the ingenious positioning of the spring (usually made of hog's bristle) the tongue pivots back, allowing the plectrum to pass the string silently on its return journey. When the jack returns to its original position a damper (made of felt) silences the vibration of the string. A piece of wood known as the 'jack rail' is fixed over the jacks to prevent them from jumping right out when the keys are pressed down. This action deprives the player of the type of contact with the string offered by the clavichord and means that basically no contrasts of dynamic or tone are possible from a single set of strings. Touch and articulation are still very important, however, and the harpsichord and virginals demand a somewhat different technique from the organ, clavichord, or piano.

The earliest detailed information we have about the construction of a harpsichord comes in a manuscript compiled in the middle of the fifteenth century by Henri Arnault of Zwolle, physician to the Duke of Burgundy;[39] the same manuscript gives details of the *dulce melos* which anticipates the piano's hammer mechanism. A German illustration of this period depicts a *clavicymbalum* with the typical winged outline which the harpsichord adopted from the wing-shaped form of psaltery, but unfortunately the artist omits the action altogether. There are a number of other representations of the harpsichord during the second half of the fifteenth century, including a stone carving in the roof of the nave of Manchester Cathedral (*c.*1465),[40] though the instrument may well have been in existence in some form as early as the beginning of the century. A German poem of 1404, *Der Minne Regeln,* lists *clavicimbalum* as well as *clavichordium* amongst the instruments of courtly love,[41] and this is the earliest recorded use of the name from which the Italian word for harpsichord *clavicembalo* derives. A common corruption is *gravicembalo* and during the baroque period the name was regularly shortened to *cembalo*. Other early names derived from the same root include the German *Klavizimbel* (though in modern German the Italian word is used) and the French *clavecinon* later shortened to *clavecin* (the word was first used by Cotgrave in 1611).[42] Since most early keyboard music left the selection of instrument to the performer it is hardly surprising that

names came to be used in a very general as well as a specific way. In the Leckingfield proverbs of Henry VII's time *clavicimbalum* probably means *claviorganum, ie* a combined harpsichord and organ; Virdung (1511) uses the word to describe a rectangular instrument, and Mersenne (1635) uses it for the carillon and keyed xylophone.[43] Praetorius (1619) pinpoints the confusion when he says that in the Netherlands the spinet is called 'Clavicymbels and also Virginals' whilst in England 'all such instruments be they large or small are termed Virginals'.[44] He also tells us that the Germans used the word 'Flügel' to describe the harpsichord because of its winged shape.[45]

The earliest harpsichord surviving today is an instrument by Jerome of Bologna dated 1521, now in the Victoria and Albert Museum.[46] It was in Italy that the first important school of harpsichord making developed and a number of other fine examples are still in existence. Several features of Jerome's instrument are typical. It is built of cypress wood and can be removed from the decorated outer case which is lined with green velvet. There are two sets of jacks and two sets of strings, but their purpose was not to offer contrast of timbre but to give extra brilliance and volume. There is no hand stop to change the registration, and both sets of jacks are permanently 'fixed on'. Although the apparent compass of the keyboard is three octaves and a seventh, the lowest note being E, the actual compass descends to C. This is achieved by a device known as 'short octave tuning'. The E key was tuned to low C, the F♯ to D, and G♯ to E. This provided an *effective* compass of over four octaves, since the missing chromatic notes – low C♯, D♯, F♯, and G♯ – were in practice not often required. An occasional variant of this system was 'split-key' tuning in which the two lowest accidentals are split into a front and a back section. The back part was tuned to its expected note, the front to the 'extra' low note. Both these devices for extending the compass were applied to other types of keyboard instrument, especially the virginals.

The second great school of harpsichord-making developed in Flanders towards the end of the sixteenth century with Antwerp as its centre, a city where instrument-makers had already flourished for over a hundred years. It was there that Hans Ruckers (*c.*1550–*c.*1620) settled down in 1575 and, after serving his apprenticeship, founded a family business which was to involve his two sons Jan (1578–1643) and Andries (1579–*c.*1645) and produce some of the most splendid keyboard instruments of the age. Ruckers instruments are often referred to during the seventeenth and eighteenth centuries; many of them continued in regular use right up to the end of the eighteenth century, and over a hundred examples of the family's work (harpsichords and virginals) are known today.[47]

The instruments built in the Ruckers workshop between the years 1580 and 1650 conformed to fairly rigid designs, and show a new aim in harpsichord-making: to offer the player some contrast of tone or register. The typical single-manual Ruckers instrument had a short-octave compass of four octaves from C and had two sets of strings, one 8-foot and one 4-foot. Hand stops in the right-hand side of the case brought one or both sets of jacks into contact with the strings as desired. The Ruckers family also produced two-manual harpsichords and they were probably the first makers ever to do so. The idea seems to have originated not as an attempt to provide more contrast but as a transposing device to help accompanists. The lower manual was pitched a fourth below the upper one,[48] so that a player could easily accommodate, for example, an alto who wanted to sing a song written in soprano pitch or a recorder player who wanted to play a treble solo on his descant. It is surprising that such transposing harpsichords are not being revived today when the facility would be as useful as ever. During the baroque period, the transposing keyboard became obsolete and both

the manuals were tuned to the same pitch so that they could be coupled together or used singly for tonal contrast or to avoid awkward hand-crossing on the same keyboard. It should be emphasized, however, that the *typical* harpsichord of the Renaissance was a single-manual instrument with one basic sound only.

**The clavicytherium**

The idea of an upright version of the harpsichord seems to have been developed as early as 1460[49] and the oldest surviving instrument – probably

Clavicytherium from Virdung's *Musica getutscht*.

Italian – is now in the Royal College of Music.[50] Although the fact that the strings were vertical made the mechanism more complicated since the jacks have to be *pulled* back instead of just falling back by their own weight, the instrument did take up a lot less space, an advantage which made it quite popular in the eighteenth century. The usual name for the instrument, *clavicytherium*, is first used by Virdung (1511) who says that the instrument is newly invented and has strings of gut.[51] Although gut strings seem unlikely, Raymond Russell points out that *clavicytherium* means *keyed lyre* and a lyre had gut strings by definition.[52] During the Renaissance the upright harpsichord does not seem to have been particularly popular, however, and as late as 1636 Mersenne still calls the clavicytherium 'a new form of spinet in use in Italy'.[53].

**The claviorganum**

The earliest reference to a sort of upright harpsichord seems to have been in combination with a positive organ,[54] and during the Renaissance a number of experimental instruments were built amalgamating different types of wind and string keyboards. The most common alignment was organ plus harpsichord, the instrument being known as the *claviorganum* (French *clavecin organisé*, German *Orgelklavier*, Italian *claviorgano*). The tuning problem of such instruments can be fairly intractable, and the simultaneous effect of two such different sounds is a delightful novelty which soon palls. Pepys put it rather nicely when he described the *claviorganum* which he heard in 1677 as 'but a bauble with a virginal joining on to it'.[54] As a two-in-one continuo instrument it was potentially very useful during the baroque period but even then it continued to be thought of as the latest invention. In 1650 Kircher illustrates a claviorganum in his *Musurgia* and considers the idea new and unheard of. Other amalgamations of the Renaissance included the *épinette organisée* (probably spinet/organ) referred to by Rabelais,[54] and a spinet-regal, an example of which survives from 1587,[55] whilst a Dresden inventory of 1593 even lists two combinations of organ with clavichord.[54] Some of the early claviorgana such as those listed in Henry VIII's Inventory[30] may have been two separate instruments without any coupling device.

**The virginals**

In spite of the English use of the word as a generic term for all types of plucked keyboard instruments, *virginal(s)* also designated a specific type. It is first mentioned by Paulus Paulirinus of Prague in *c.*1460[56] and the name was used in France and Germany as well as England. The origin of the word is not English nor has it anything to do with Queen Elizabeth I as has been often stated, although she certainly did play the instrument.[57] Virdung (1511) mentions the virginals but says that he knows nothing of its origin or invention.[58] Although Curt Sachs derives the name from the Latin *virga* meaning a rod (diminutive *virgula*) because of the virginals' jacks,[59] and Sibyl Marcuse from the fact that the frame drum of ancient East Mediterranean culture was traditionally played by women,[56] the most widely accepted view is that the name is related to the young ladies who are so regularly depicted playing the virginals.[60] There was certainly a standing joke on the subject during the Renaissance which ranged from the fairly decorous, as on the title-page of *Parthenia* (1611), to the downright ribald as in Ben Johnson's *The Alchemist* where Face says to Dol:

Sweet Dol
You must go tune your virginal.[61]

The main differences between the harpsichord and virginals lie in the shape of the soundbox, the placing of the strings, and the existence of two bridges on the latter instrument. The typical virginals is oblong with the strings running parallel to the keyboard instead of at right-angles to it. With the exception of the double virginals already mentioned, there was only one set of strings and no change of timbre was possible. Praetorius, however, mentions the *Arpichordum* as a type of virginals on which 'a

harp-like sound is produced by means of a special stop which governs metal jacks under the strings'.[62] This is evidently a special effect similar to the buzzing or rattling produced by the 'bray'-pins of the harp which Praetorius described as *harfenierend* (see chapter 4 page 22).

The placing of the keyboard on virginals varied; on Flemish instruments it was set either to the right or left and in 1699 Klaas Douwes explains that the name *muselar* was used for the former type of instrument and (confusingly) *spinet* for the latter.[63] Different placings of the keyboard involved different placings of the jacks in relation to the strings and the tone varies considerably according to where the

strings are plucked. Writing in 1739 another Dutchman, Quirinus van Blankenburg, relates: 'of the virginals we will say in passing that those whose keyboard stands towards the left are even and playable . . . but those which have the keyboard on the right-hand side are good in the right-hand, but grunt in the bass like young pigs.'[64] The compass of the virginals built by the Ruckers family was the same as that of their single-manual harpsichords, four octaves from C, with short-octave tuning in the bass.

**The spinet**

On the spinet the strings either run diagonally in front of the player or more or less parallel to

the keyboard as on the virginals. The typical spinet form is an uneven six-sided shape with the longest side containing the keyboard. Normally there was one set of strings and a four-octave compass. The French word *épinette* and the Italian *spinetta* were applied fairly indiscriminately to all types of plucked keyboard instruments, rather in the same way that *virginals* was used in England. Various explanations have been given for the origin of the name, which occurs as early as 1496.[65] The Italian composer Banchieri made the suggestion in his *Conclusioni* (1609) that the spinet was named after Giovanni Spina, the maker of an instrument dated 1501 which Banchieri had seen.[65] Another theory is that the derivation is from the spinet's thorn-like plectra, *spinetta* being the diminutive of the Italian *spina*, a thorn. As Sybil Marcuse says, neither the etymology nor the early history of the instrument is at all clear.[65]

Praetorius[66] and others suggest that the spinet

was a small instrument, tuned a fifth or an octave higher than normal. On some double virginals the second keyboard was tuned an octave higher and the production of such 4-foot instruments led to the use of the name *spinetta ottavina* or simply *ottavina*.

**The geigenwerk**

In 1604 Praetorius entered the service of the Duke of Brunswick and was very impressed by a new instrument which the Duke had recently acquired. This was the *Geigenwerk*, invented in about 1570 by Hans Baiden of Nuremberg and developed by him over the next thirty years. Praetorius devotes a disproportionate amount of space to the invention in his *Syntagma Musicum* and quotes approvingly from Baiden's own writings on the subject.[67] The Geigenwerk was in essence a super-mechanized version of the hurdy-gurdy, with brass and steel strings activated by five or six parchment-covered wheels set in motion by a treadle. Perhaps the most remarkable feature was its ability to obtain *piano* and *forte*: the harder a key was pressed down the louder the sound became. Baiden made at least twenty-three such instruments[68] though none of them seems to have survived. A Spanish imitation of the Geigenwerk, dated 1625, is preserved in the Brussels Museum of Musical Instruments.[69] Samuel Pepys heard a similar kind of instrument called the *Arched Viall* at a meeting of the Royal Society in 1664. His verdict was: 'it will never do. But after three hours stay it could not be fixed in tune and so they were fain to go to some other musique of instruments.'[70]

Whilst their medieval predecessors had enjoyed a fairly restricted musical usefulness, brass instruments found an entirely new lease of life during the Renaissance. The developments which took place during the second half of the fifteenth century were little short of revolutionary, and for the high standard of brass playing which undoubtedly existed during the sixteenth century much of the credit must go to the craftsmanship of the makers. The art of instrument-making in general achieved a new delicacy and finesse during the Renaissance. But whereas the improvements on strings and woodwind lay mainly in the *details* of construction, on the brass instruments the changes were fundamental and opened up new horizons of performing technique. By about the year 1500 the cornett had developed the various forms which remained unchanged throughout its career, the natural trumpet had established the shape it was to maintain for three hundred years, whilst the slide principle of the sackbut has never been improved upon and the modern trombone still adheres to the same basic design.

Besides their obvious exterior features the trumpet and sackbut also benefited from the tremendous improvements in metal-working which took place during the Renaissance.[1] Bending a thin-walled copper tube through a 180° curve without distorting the bore is a tricky process, but new alloys, precision tools, and new techniques in casting produced brass instruments which set a new standard in matters of intonation and tone quality. Many of them, especially the ceremonial trumpets, were often gorgeously decorated and engraved and deserve to be considered as works of art in their own right. One particularly important acoustical development was the exponential bell[2] which projects sound more effectively than a simple funnel of cone shape.[3] The great European centre for making brass instruments was the city of Nuremberg and Don Smithers lists the names of over sixty individual makers who worked there between 1500 and 1800.[4] Many of them operated family businesses which flourished for several generations and in the early period the leading name is unquestionably that of Neuschel. In his *General History of the Science and Practice of Music*, Sir John Hawkins says: 'The trumpet is said by Vincentio Galilei . . . to have been invented at Nuremberg; and there is extant a memoir which shews that trumpets were made to great perfection by an artist in that city, who was also an admired performer on that instrument, it is as follows; "Hans Meuschel [*sic*] of Nuremberg, for his accuracy in making trumpets, as also for his skill in playing on the same alone, and in the accompanyment with the voice, was of so great renown, that he was frequently sent for to the palaces of princes the distance of several

hundred miles. Pope Leo X, for whom he had made sundry trumpets of silver, sent for him to Rome, and after having been delighted with his exquisite performance, dismissed him with a munificent reward." '[5] Whilst Don Smithers considers it doubtful whether Nuremberg produced the first true trumpets,[6] the Neuschel family achieved a high reputation for their skill during the Renaissance, and made a significant contribution to the development of both the trumpet and sackbut.

In spite of the transformation in construction and appearance, brass instruments retained their old associations and specific functions. Mention is made below of the use of the trumpet as a watchman's instrument, but the great glory of the renaissance brass family was the ceremonial music which it could provide for every important occasion, state or civic. As Mersenne says of the trumpet: 'they serve in time of peace and war for all sorts of public celebrations as is seen in marriages, banquets, tragedies and carrousels'.[7] Brass instruments regularly contributed to the pageantry of a royal procession or added to the glamour of civic ceremony. The Italian Vizani, writing in 1602, describes the public appearances of the dignitaries of the city of Bologna as follows: 'When they appear in public, these "Signori" are dressed in rich robes of silk, and during the winter they are muffled up with very precious furs as well. They are accompanied by a very respectable household of eight trumpeters, with a drummer or player of the nakers, who with these trumpets plays certain Moorish drums. To both the drums and the trumpets are attached banners with the arms of liberty; also eight

excellent musicians with trombones and cornettos; a herald; a "spenditore"; nine pages dressed in scarlet cloaks and stockings in the livery of the city – white and red . . .'[8]

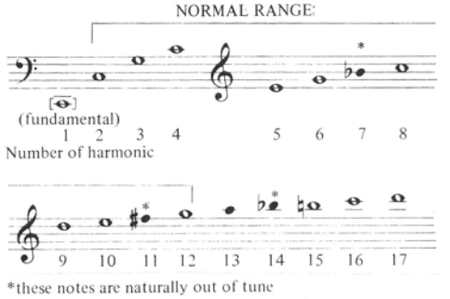
Other sources tell a similar story. In the grand cortège of musicians included in the *Triumph of Maximilian I*,[9] designed to honour the Holy Roman Emperor, pride of place is given to trumpets and sackbuts along with shawms and rauschpfeifen. A study of the English royal household accounts from the reign of Henry VIII to Elizabeth I reveal that at any given time there were more trumpeters on the payroll than any other type of instrumentalist.[10] At the coronation of Elizabeth in 1558 there were seventeen trumpeters, six 'sackebutts', and other 'musicians' who may well have included cornett players.[11]

**The trumpet**

In his *Musica getutscht* (1511) Virdung makes some interesting distinctions between different shapes and types of trumpet. He illustrates the *Thurner Horn* (a true trumpet in spite of its name) which displays the old-fashioned S shape frequently illustrated during the fifteenth century. It was from this S-shaped form of *buisine* that the slide trumpet had developed (see chapter 3, page 20). The name *Thurner Horn* means tower-horn, *ie* the instrument with which tower watchmen were equipped in order to raise the alarm in case of attack, fire, or some civil disturbance. In Amsterdam and Hamburg in the seventeenth century it was noted that: 'When a Fire happens by Night, the Trumpets plac'd upon the Towers shall sound an Alarm, and hang out two Lanthorns to the Quarter, where the Fire is, and one on the other side.'[12] The tradition was of long standing: the 1452 fire regulations of Cologne state that when a fire is detected the watchers on the town-hall tower shall first sound their trumpets and then strike the fire bell.[13] As early as 1372 there were restrictions on trumpet-playing to avoid giving a false alarm: in that year in Paris unofficial trumpet-playing after the hour of curfew was made a crime, except at weddings.[14] All the same it is difficult to see why the old-fashioned S-shaped instrument should have been preferred for tower duties. As Philip Bate suggests,[15] it may be just that the military trumpeters, who were already forming themselves into unofficial guilds, liked to keep the more up-to-date instruments to themselves.

Virdung calls his other two trumpets the *Clareta* (from the same root as *clarion*) and the *Felttrummet* (field-trumpet). Both show the twice-folded oblong form of the natural trumpet. At this time a change in terminology seems to have been taking place. In 1519 the historian William Horman stated that 'A trumpette is streyght; but a clarion is wounde: in and out with an hope [*ie* hoop]'[16] and a distinction between the two was made as early as 1346 when the English army at the battle of Crécy was heralded by clarions as well as trumpets.[17] At that stage, however, nomenclature was anything but standardized. It seems likely that the clarion was associated with playing in the upper register (Virdung's *Clareta* appears to have a narrow bore which would favour the production of the higher harmonics). This would certainly explain the use of the word *clarino* during the baroque period for the trumpet's brilliant upper register. The foundation for the virtuoso lip technique which baroque trumpeters displayed must have been laid during the late Renaissance though it does not become apparent until the beginning of the seventeenth century.

Praetorius (1619) and Mersenne (1635) both illustrate the standard natural trumpet: clearly the different transitional types of Virdung's time have merged into one. Praetorius tells us: 'The trumpet . . . is a magnificent instrument. It is remarkable that in its higher register this instrument affords conjunctly almost all the diatonic notes and various chromatic notes as well.'[18] By this time we have the first surviving example of the sort of elaborate polyphonic fanfare which the trumpet bands of the late



Range of the natural trumpet in C. In practice the fundamental was not used and trumpeters divided the rest of the compass between them. Praetorius gives g″ as the highest normal note, but 'falsetto' notes as high as the f‴ above. It seems likely that this is a misprint for d‴.

Renaisssance must have played. This is the *Toccata* from Monteverdi's first opera *Orfeo*,[19] performed in Mantua in 1607, and the scoring shows the sort of division of labour which became characteristic in baroque trumpet playing. The top part, labelled *clarino*, lies in the top register between c'' and a'' (employing the eighth to the thirteenth harmonics). The second part involves only four notes of the common chord of C (c', e', g', c'') whilst the third lies lower still (g, c', e'). Baroque trumpeters customarily specialized in one register only and were paid according to how high they went. Even today, with the facility of the modern valve trumpet, players who specialize in the first trumpet parts of Bach and Handel would seem to deserve something very like danger money.

Monteverdi's instruction for the performance of the Toccata is interesting because he mentions the effect of mutes. 'Si fa un Tuono piu alto volendo sonar le trombe con le sordine'[19] (those wishing to play the trumpets with mutes make it a tone higher). Early trumpet mutes were totally different in shape from modern ones, as Mersenne's illustration shows, and they not only reduced the tone and volume drastically but acted as a transposing device as well. They were inserted so far into the bell of the instrument that they raised the pitch by a whole tone. There can be little doubt that the Toccata which starts *Orfeo* should sound in D major, not in C as written, and thus match the D minor of the ensuing ritornello.[20]

According to Praetorius, military trumpets were normally pitched in D which had been the standard key for all trumpets to be built in. However, he tells us that court trumpeters had recently taken to using crooks to lengthen the tube and lower the pitch to C or even B flat.[21] Praetorius also illustrates two other types of trumpet: a straight wooden one, virtually identical to that still used by Scandinavian shepherds (see chapter 3 page 19) and a *Jäger Trommer* or hunting trumpet which shows the coiled form adopted by some later German makers. Some of the secrets of trumpet-playing are for the first time revealed in the *Modo per Imparare a sonare di tromba* published by Girolamo Fantini in 1638.[22] This is the first printed tutor for the trumpet and includes tonguing exercises, battle calls, and some pieces for one and two trumpets with continuo. By this time the words *trompette* (French), *tromba* (Italian), and *Trompete* (German) had come into general use to describe the natural trumpet, though the French word *trompe* signified horn, as the Spanish *trompa* still does to this day.

### The horn

In a paper written in 1775 entitled 'Of the Horn as a Charter or Instrument of Conveyance' Samuel Pegge describes horns as being of four sorts: drinking horns, hunting horns, horns for blowing, or horns for drinking, a stopper being provided for the last-named purpose.[23] If we may borrow his classification for the sixteenth century, it neatly epitomizes the horn's backward state of development and limited musical function. Nevertheless the horn began to be regularly made of metal during the late Renaissance, and makers experimented with

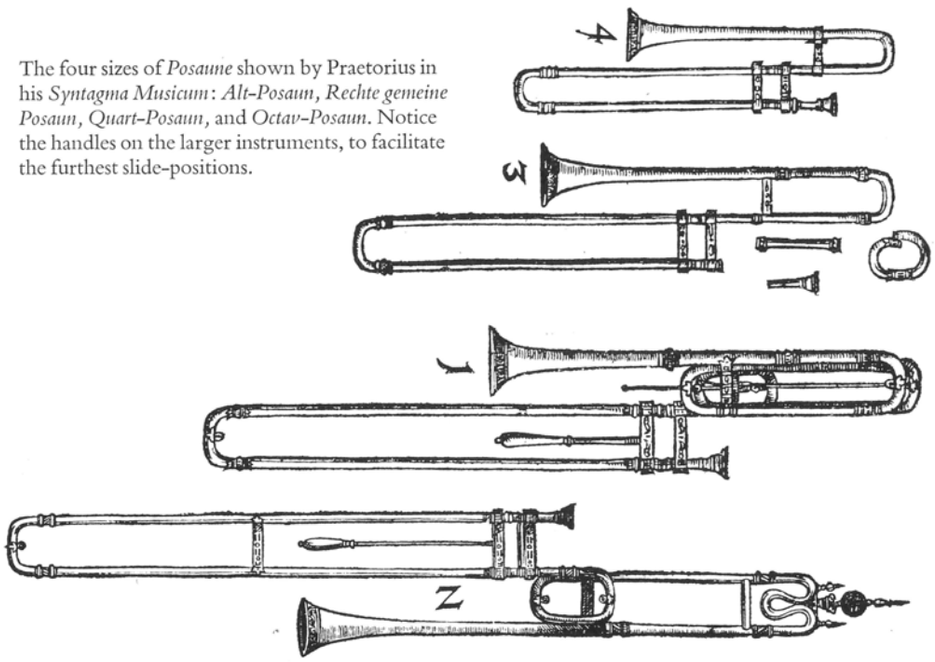
different types of curvature and coiling as can be seen from Mersenne's illustrations. The seventeenth-century *cor de chasse* developed from a combination of two of the types he shows: the tightly coiled *helical* horn (labelled A) with the slender crescent-shaped horn (labelled B) with one coil in the middle. It is interesting that Mersenne mentions the playing of *part* music on horns. 'If the hunters wish to have the pleasure of performing some concerts in four or more parts with their horns, it is rather easy, provided they know how to make their notes exact and they so proportion the length and thickness of their *trompes* [*ie* horns] that they maintain the same ratios as organ pipes.'[24] And Mersenne goes on to explain the necessary sizes for a horn consort. The first surviving horn fanfare comes in Cavalli's opera *Le nozze di Teti e di Peleo* (1639).[25] Although written in five parts it consists of a simple reiteration of the chord of C major and may well to some extent represent earlier practice. From the sixteenth century we have only isolated hunting calls, though the sound of horns was occasionally imitated in polyphonic music. Edward Piers' madrigal *Hey, trola, there boys there* (1614)[26] contains an elaborate imitation of hunting calls and it has even been suggested that the tenor and bass parts of Gombert's programme-chanson *La Chasse de Lièvre* could be played on horns in F.[27]

### The sackbut

The origin of the word 'sackbut' remains uncertain. According to Galpin[28] it derives from the fourteenth-century Spanish *sacabuche* meaning literally 'draw-pipe'. Sachs[29] thinks that a more likely derivation is from the French *saquer* (to pull) and *bouter* (to push): the word



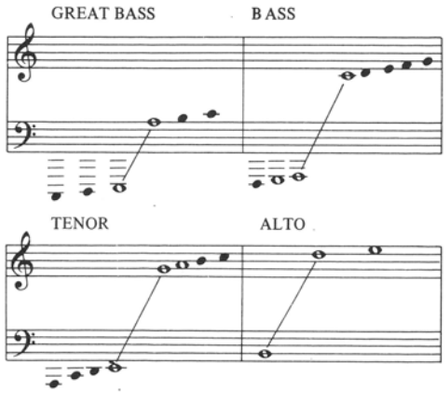
The four sizes of *Posaune* shown by Praetorius in his *Syntagma Musicum*: *Alt-Posaun, Rechte gemeine Posaun, Quart-Posaun,* and *Octav-Posaun*. Notice the handles on the larger instruments, to facilitate the furthest slide-positions.

Tenor, alto, and soprano sackbuts. The water-keys are a modern addition. Tenor: Neuschel copy mentioned above. Alto: adapted from an undated alto trombone by Peerless. Soprano: made by Finke, based on various originals.

*saqueboute* is used from 1466 onwards, often in the form *trompette saqueboute*.[30] Whatever the origin, this foreign name certainly puzzled the English keepers of royal records and household accounts and from 1495 onwards references include: *shakbusshes*,[31] *seykebuds, sakbuds, shakebuttes, shagbutts*,[32] and even *shagbolt*.[33] The other basic names for the instrument emphasize its relation to the trumpet: *trombone* (in French and Italian as well as English) derived from *tromba*, and the German *Posaune* derived from *buisine*. Virdung uses an intermediate spelling *Busaun*. Less common names included *tromba spezzata, trompette brisée,* and *trompette harmonique*, this last being used by Mersenne.

Equally uncertain is the date of the sackbut's first appearance. There is an interesting account of the manner in which English prelates were received on their entry into the Council of Constance (1414–18): 'die pusauner pusaunoten über einnander mit dreyen stymmen, als man sunst gerwonlichen singet' (the trombonists tromboned together in three parts as one is otherwise accustomed to sing).[34] At this stage *pusauner* might have referred to some kind of slide trumpet or even still meant the old *buisine*, though it is difficult to imagine three buisines playing in parts 'as one is accustomed to sing'. By a curious coincidence two three-part pieces survive from the beginning of the fifteenth century which have a suggested instrumentation involving some kind of trumpet. They are *Virgo dulcis* by Henricus de Libero Castro, with its tenor marked 'Laudate eum in sono tube' and contratenor marked 'Tube', and the anonymous *Tuba gallicalis*, which is in the nature of a fanfare.[35] The source of both pieces is the lost Strasbourg manuscript and the restricted range of parts is almost identical in both (c–g′ overall). Both pieces contain the note d, however, outside the compass of the slide trumpet, and it is possible, as with the contratenor *Trompette* by Dufay (see chapter 3, page 20), that the pieces were designed for an early form of sackbut.

It must be admitted, however, that evidence for the practical employment of the sackbut is scanty before the last years of the fifteenth century; yet it represented such a useful addition in the brass family that one imagines its use spreading rapidly. Writing in about 1487, Tinctoris gives us this valuable piece of information. 'However for the lowest contratenor parts, and often for any contratenor part, to the shawm players one adds brass players who play, very harmoniously, upon the kind of tuba which is called . . . *trompone* in Italy and *sacque-boute* in France. When all these instruments are employed together, it is called the loud music'.[36] From 1500 onwards the sackbut is illustrated and mentioned regularly and the Neuschel family produced sackbuts as well as trumpets (see page 65). However, really detailed information is not available until the early seventeenth century. Praetorius gives four principal sizes with their ranges.



Sackbut ranges from Praetorius' *Syntagma Musicum*.

He makes it clear that the most useful size is the tenor in B♭ (the *Gemeine Rechte Posaun*) which can cope with alto, tenor, or bass parts. This was the standard instrument used by the leading players of the time and Praetorius singles out two virtuosi for special mention. The 'famed master', Phileno of Munich, could manage a range of D–e″ 'without any difficulty' whilst Erhardus Borussus whom Praetorius heard in Dresden was apparently capable of quite astonishing feats unrivalled even today. He not only had a range of nearly four octaves from low A′ to high g″ but 'was able to execute rapid coloraturas and jumps on his instrument just as is done on the *viola bastarda* and the cornett'.[37] Praetorius stresses that a tremendous advantage enjoyed by all sackbuts was their adaptability to the various different pitches of the day. Small changes could be made by slide or embouchure, larger changes by the addition or subtraction of crooks or other sections of tube. Praetorius also mentions an alternative size of bass sackbut (a *Quint Posaun* in E♭) and there may well have been an alto in E♭ too, paving the way for the later orchestral alto trombone in the same key.

Mersenne (1635) adds two other particularly interesting pieces of information.[38] In the matters of sound production the player should imitate the cornett, rather than the trumpet, presumably to obtain flexibility and expressiveness of tone. Mersenne also emphasizes the importance of the sackbut's crooks and explains how the stays joining adjacent sections of parallel tube were detachable so that the instrument could be conveniently dismantled. On the Neuschel sackbut of 1557 (see page 65) the bell stay is fixed, whilst those at the top of the slide and at the mouthpipe are movable.[39] Apart from this, the only important feature which distinguishes a modern trombone from its predecessor is the greatly increased flare of the bell. It is strange that despite its considerable range of dynamics, wide chromatic compass, and secure intonation the trombone did not become a regular member of the orchestra long before the early nineteenth century. Part of the reason may lie in the trombone's use as a 'special effects' instrument. Monteverdi uses a consort of *tromboni* in Act III of *Orfeo* to create the awesome mystery of the Underworld. Coupled with the sinister sound of the regal the effect is spine-chilling, and when Mozart introduced trombones into the last act of *Don Giovanni* he was drawing on an old association.

Although Praetorius calls the smallest size of sackbut *alt* or *discant* there was, in fact, no trombone small enough to cope with real treble parts during the Renaissance. For outdoor music the proper treble instrument for a consort of sackbuts was the shawm; for more sophisticated indoor music and especially for doubling the voices in church the cornett provided the ideal

partner. One or two pieces were written for this specific combination including the *Sonata Pian' e Forte* and other canzonas in Giovanni Gabrieli's *Sacrae Symphoniae,* published in 1597,[40] as well as Matthew Locke's *Music for His Majesty's Sackbuts and Cornetts* of 1661.[41] During the seventeenth century the sackbut even developed a small solo repertoire, mainly from composers associated with the Viennese court of the Holy Roman Emperor Leopold I. No doubt the existence of virtuosi such as those mentioned by Praetorius, coupled with the high standard of German-made instruments, encouraged composers such as Heinrich Biber and Johann Schmelzer to include the sackbut along with the violin and cornett in some of their sonatas, and to write the same kind of scales, trills, and decorations as they did for the more naturally agile treble instruments. The end of the seventeenth century, however, witnessed a decline in the playing of both shawm and cornett and this was probably the reason for the development of the soprano sackbut, pitched in B♭ an octave above the tenor, in order to complete the family. The earliest instruments of this size seem to have been made in Germany and Sweden.[42]

**The cornett**

The most versatile wind instrument of the Renaissance was undoubtedly the cornett. During its heyday – roughly 1500 to 1650 – cornetts were in demand for music of all kinds: indoors and outdoors, in serious music and dance music, in church and chamber, in the town bands and royal households. The highly individual qualities of the cornett stem from the fact that the instrument is a compromise: a hybrid form which combines the cup-mouthpiece technique of the brass with the finger technique of the woodwind. Hence its astonishing versatility: in the hands of a skilled player the cornett can sound as loud as the trumpet or blend with a recorder; it can outshine the violin in brilliant divisions or sing like a human voice. No other instrument had such a vocal quality; when, in 1742, Roger North reminisced about the depleted state of choirs after the Commonwealth he said: 'To say the truth nothing comes so near, or rather imitates so much, an excellent voice as a cornet pipe.'[43] Earlier he had expressed himself more succinctly: 'One might mistake it for a choice eunuch.'[43] Perhaps the most poetic and evocative description of the cornett's unique tone quality comes from Mersenne: 'Il est semble à l'esclat d'un rayon de Soleil, qui paroit dans l'ombre ou dans les tenèbres, lors qu'on l'entend parmi les voix dans les Eglises Cathedrales, ou dans les Chapelles.' (It seems like the brilliance of a shaft of sunlight appearing in the shadow or in darkness, when one hears it among the voices in cathedrals or in chapels.)[44]

The cornett emerged in its various renaissance forms towards the end of the fifteenth century, although the word is mentioned as early as about 1400.[45] The spelling with a double 't' was by no means standard in English, but is generally used today to avoid confusion with the nineteenth-century band instrument. The name means 'little horn', being a diminutive of the Latin *cornu,* hence the Spanish *corneta* and the Italian *cornetto* and *cornettino* (the latter a double diminutive). The French developed the name *cornet à bouqin* (cornett with a mouthpiece) whilst the typical German word was *Zink.*

Whatever their shape or method of construction all cornetts have some kind of cup-mouthpiece and seven holes, usually six finger-holes and a thumb-hole or in the case of some French instruments seven finger-holes and no thumb-hole. In spite of the absence of a seventh hole for the little finger, players were expected to be able to produce the missing note by slackening their embouchure or 'lipping down'. For the standard cornett in G, for example, the same fingering (all holes covered) is used for g, a♭, and a – see fingering chart. On the large tenor cornett a seventh finger-hole plus open-standing key was sometimes provided to give a firm bottom C. Nor is the rest of the cornett's fingering system quite as straightforward as that of woodwind instruments, and in any case the player still has to 'make' the notes with his lips: the finger-holes make them possible rather than probable. Altogether the cornett offers formidable difficulties of technique: a playing position which can quickly tire the fingers, an embouchure which can quickly tire the lips, and enormous problems of intonation and smoothing out the basic inequalities of the tone between 'covered' and 'open' notes. The more holes there are uncovered, the more difficult it is to achieve a good sound.

Yet renaissance players seem to have solved all the problems and there are many accounts of the cornett's agility as well as beauty of tone. Here is the Italian Bottrigari writing in 1594:

'Cornetts and trombones are played with such grace, taste and sure precision of the notes, that they are held the most excellent of the wind instruments in the profession. Their divisions are neither scrappy nor so wild that they spoil the underlying melody and the composer's design: but are introduced at such moments and with such vivacity and charm that they give the music the greatest beauty and spirit.'[46]

The secret of cornett playing clearly lies in the embouchure. Most professional cornettists today are also trumpet players and use a trumpet-style mouthpiece placed in a central position on the lips. Renaissance players favoured the smaller acorn-shaped mouthpiece often placed at the side of the mouth where the lips are thinner. Such an embouchure, whilst incompatible with modern brass techniques, must have made softer sustained playing easier. Mersenne tells us that two special attributes of the cornett are its ability to play as softly as the flute and the way it uses up very little breath. He mentions one of the French royal musicians, M. Quiclet, who could play for eighty measures without breathing ('which surpasses all credence') and the even more redoubtable M. Sourin of Avignon who could manage a hundred measures in one breath.[47]

Memoirs and reminiscences by professional instrumentalists are notably lacking from renaissance times but we do have a first-hand account from one cornett player, that true child of the time Benvenuto Cellini. He was born in 1500, and although his father made him play the flute, which he loathed, he also took up the cornett. Shortly after he set himself up in Rome in 1519 as a jeweller and goldsmith he took on a young apprentice called Paulino to whom he became rather attached. Cellini tells us in his autobiography: 'I loved him so passionately that I was always playing music for him in order to see his lovely face, which was normally rather sad and serious, brighten up when he

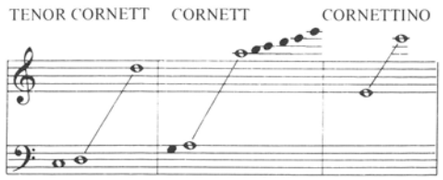
heard it. Whenever I took up the cornett, such a frank, beautiful smile came over his face that I am not at all surprised at those silly stories the Greeks wrote about their gods . . . He had a sister called Faustina who was even more beautiful, I think, than the Faustina the ancient books are always babbling about. Sometimes I used to visit their vineyard and from what I could judge it appeared to me that Paulino's father, a thoroughly worthy man, would have liked me as son-in-law. All this made me play a great deal more than usual.'[48]

According to Benvenuto Cellini it was his mastery of the cornett which brought him into contact with Pope Clement VII. One of the Pope's musicians sent a message to Cellini 'asking me if I would help them at the Pope's August festival in some very beautiful motets they had chosen, by playing the soprano part on my cornett. Although I was burning to finish my wonderful vase, as music is a marvellous business anyway, and to give my father some satisfaction, I was quite ready to join them. We spent a week before the festival practising together two hours a day. On the day itself we went along to the Belvedere, and while Pope Clement was having dinner we played the motets we had rehearsed so well that he had to admit he had never heard music played more exquisitely or more harmoniously.'[49]

And Cellini goes on to say that the Pope offered him a job on the spot. During the years 1523 to 1540 Benvenuto Cellini certainly served Clement VII and his successor Paul III not only as artist and craftsman, but as soldier and gunner as well.

It would be interesting to know what type of cornett Benvenuto Cellini played, though unfortunately he gives us no details. By his time there were basically three varieties – curved, straight, and mute – all made in different sizes. The earliest to develop was probably the straight cornett (*cornetto diritto, gerader Zink*) which is the only type shown by Virdung in his *Musica getutscht* (1511). This was usually turned on a lathe instead of being made in two halves (see below). Because of the finger stretches involved it was impossible to make straight cornetts in sizes larger than the alto. In any case the curved form was obviously regarded as more comfortable and largely superseded the *diritti* during the course of the century. Straight cornetts continued to be made up to the nineteenth century, however.[50] The mute cornett (*cornetto muto, stiller Zink*) was also straight, but instead of having a separate detachable mouthpiece, a conical recess was cut into the top of the instrument itself, as on the *tuohitorvi* (see chapter 3, page 20). The formation of this mouthpiece, in particular the very wide throat, combined with a narrower bore, made the mute cornett an exquisitely soft instrument, ideal for playing with the recorder, lute, or viol.[51]

The favourite form of cornett was the *cornetto curvo* or *krumme Zink,* sometimes also described as *nero* or *schwarz* because of the black leather covering. The bore of the instrument is made in two gouged-out halves, like the tuohitorvi. Then the inside is smoothed off and the two halves glued together. The outside is planed to a very beautiful eight-sided shape and finally the leather is glued round the outside in a single piece. This is mainly to seal any leaks which might develop along the bore. For similar reasons, cornetts were sometimes decorated with silver rings to strengthen the instrument at judicious points.[52] In one of the more spectacular performances of the Monteverdi *Vespers* (1610) in recent times, one cornett did literally come unstuck. Whether it was the high notes it had been playing, the cold temperature in the chapel, or a glue weakened after 300 years, the two halves of the cornett just came apart in the player's hands. In fairness it must be said that the taxing solo parts in the Vespers, particularly the *Sonata sopra Sancta Maria* and the obbligato in the *Deposuit* (which takes both instruments up to top d″), are enough to make any cornett want to fall apart. But this was the way composers treated the cornett: as a virtuoso instrument. Monteverdi's *Orfeo* (1607) also features the cornett, and a common inscription for early seventeenth-century instrumental parts was 'per cornetto overo violino', showing that the cornett was in every way as proficient as the violin.



Cornett ranges from Praetorius' *Syntagma Musicum.*

The standard size of cornett (straight, curved, or mute) was pitched in G giving a comfortable range of two octaves, extended by exceptionally proficient players as Praetorius shows. The *cornettino,* pitched a fourth or fifth higher in C or D, was a useful instrument for high parts, like those of Monteverdi, though it seems to have been much less common. There were also alto cornetts in F, a tone below the standard cornett: a mute cornett of this size was probably in use at Kassel when Schütz was a boy chorister there. The tenor cornett in C was so large that it necessitated two curves in the tube instead of one; hence an English name *lysarden* or lizard. Praetorius, who tells us that it was also called *Cornon,* is fairly disparaging about the tone, describing it as 'unlovely and horn-like'[53] in its lower register. Because of its wider bore the tenor cornett is really more like the serpent: the sound makes a good blend with voices but lacks the individual timbre of the higher cornetts and consequently was not much used for solo work. It was used in consort, however, and Anthony Baines[54] points out that the *Fugen* or canons by Johann Walther, published in 1542 and marked 'especially for cornetts', require a tenor cornett for the bottom part.[55]

During the baroque period the cornett was gradually eclipsed not only by the baroque trumpet with its *clarino* technique, but by the baroque oboe too, which was easier to play in tune. Although Bach scored for the cornett in eleven of his cantatas it was always in a supporting rather than a solo role. But it is remarkable just how long the tradition of cornett playing survived. For a century after the cornett had fallen into disuse one or two German town bands kept the tradition going. As late as 1840, the French composer and historian Kastner actually heard the sound of cornetts and trombones coming from the church tower in Stuttgart: a town band still playing their daily chorales in the old German manner.[56] A few years later came the beginning of our modern interest in the sounds and the instruments of the past. But it came just too late – there were no cornett players left and the secrets of their art were buried together with a fascinating link with the playing traditions of the Renaissance.

**The serpent**

'But the true bass of the cornett is performed with the serpent, so that one can say that one without the other is a body without soul.' So writes Mersenne,[57] though he does not seem

to know the instrument's origin, merely telling us that the sackbut is believed to be 'more ancient'. The serpent is thought to have been invented in about 1590 by a canon of Auxerre, one Edmé Guillaume.[58] Whilst this remains a moot point, the earliest use of the instrument does seem to have been confined to France where it was an ecclesiastical instrument used to double men's voices. When it is well played, the serpent blends perfectly with a choir, losing its own individual timbre altogether, whilst giving an extra depth and fullness to the vocal sound. The serpent is not mentioned by Praetorius and its popularity spread only gradually during the seventeenth century. During the next two hundred years it enjoyed a flourishing career as a military band instrument and serpents were still in use in some of the English church bands of the late nineteenth century.

The *serpent d'église* as described by Mersenne was a keyless instrument with six finger-holes and a fundamental of E. It consisted of a conical tube over six feet long with a more widely expanding bore than any type of cornett (later serpents were rather larger and pitched in D or C). It was usually made in two halves which were glued together and bound with leather and it had an elbow-shaped brass crook to adjust the mouthpiece to a comfortable position. The serpentine contours of the instrument,

necessary to bring the holes and mouthpiece within reach of the player, seems to have given rise to similar names in every language: *Serpent* in German, *serpentone* in Italian, and *serpentón* in Spanish. Mersenne makes the surprising statement that 'it is so easy to play that a child of fifteen can sound it as easily as a man of thirty'.[59] In practice, great skill and musicianship are required, since every note depends on the player's embouchure and sense of pitch. The capricious nature of the instrument is shown by the various fingering charts published during the eighteenth and nineteenth centuries, no two of which agree about details of fingering or compass.[60] Certain notes can be lowered a fourth or more by slackening the embouchure and a favourite trick of some serpent players today is to play an *upward* scale whilst fingering a *downward* one. Nevertheless, the published tutors for the instrument[60] do prescribe a range of over three octaves and a degree of virtuosity which was perhaps not so common in the early days when the serpent's duty was to be seen rather than heard.

# 9 Strings

There can be no doubt of the pre-eminence of stringed instruments during the Renaissance, both in theory and in practice. Through a largely imagined inheritance from the instruments of the Ancients they were endowed with an allegorical and symbolic significance, faithfully represented in countless books and paintings. As a result of their wide compass and innate ability to match the human voice, they were indispensable to virtually all forms of indoor music-making, from dance music to church music. In the hands of the renaissance makers stringed instruments attained a new perfection of form and design which attracted amateurs and professionals alike. It was principally for strings that the various purely instrumental forms of ensemble music developed such as the fantasy, canzona, *in nomine*, and the new dance types. Like keyboard instruments, the strings developed a vast solo repertory with their own idiomatic forms of the prelude, ricercar, and *tastar de corde*. The amount of music specifically written for stringed instruments during the sixteenth century is enormous. A glance at Howard Mayer Brown's *Instrumental Music printed before 1600*[1] reveals the overwhelming proportion of publications devoted to string music, with the lute taking the lion's share. Yet this is merely the tip of the iceberg: the manuscript sources, particularly those for the lute or viol families, contain a vast repertoire which has not yet been fully explored in modern times.

Considering the daunting amount of material to be assimilated it is perhaps not surprising that the definitive account of most sixteenth-century stringed instruments remains to be written.[2] It is an area in which much research has been done in recent years and one in which exciting discoveries are still being made, amongst them the *Board Lute Book*,[3] unearthed by Robert Spencer, which contains over 188 pieces, a hundred of which are unique in some way, and the broken-consort lessons which came to light in the North Humberside County Record Office, Beverley.[4] The fruits of recent research are to be found in the various periodicals regularly mentioned in this book, particularly the *Lute Society Journal* and the *Journal of the Lute Society of America*. Both these journals deal regularly with other plucked instruments besides the lute and occasionally with bowed instruments as well.

Amongst the very varied repertoire for mixed string ensemble it is not mere chauvinism which leads one to single out Thomas Morley's *First Book of Consort Lessons*[5] of 1599 as a most remarkable and rewarding collection. The question of the flute/recorder part has already been mentioned in chapter 6, as has Praetorius' enthusiastic description of the novel and extraordinary effect of the English broken consort.[6] It is worth adding that the very careful scoring for the stringed instruments (viols, lute, bandora, and cittern) particularly in the pieces by Richard Allison, gives us a fascinating insight into contemporary habits of chordal accompaniment, making divisions, and ensemble playing. The roles of each instrument are so distinct, the arrangements so carefully worked out, and each part so perfectly suited to the instrument that Morley's book clearly represents a culminating point rather than the beginning of a tradition. The broken consort had a particular association with the private theatres. At Blackfriars, where the boys of the Chapel Royal acted, a foreigner wrote in 1602: 'For a whole hour preceding the play one listens to a delightful entertainment on organs, lutes, pandoras, mandoras, viols and pipes.'[7] The broken consort must have provided some of the incidental music to the plays themselves too. No better combination of soft instruments could be found for that tricky theatrical situation, music under dialogue, such as that commanded by Lorenzo in the last scene of *The Merchant of Venice* or implied by Orsino's famous opening line in *Twelfth Night*. Indeed, details of stringed instruments and their technique are woven throughout the whole fabric of Elizabethan and Jacobean literature.[8] Hamlet's remarks, to Rosencrantz and Guildenstern, 'you would pluck out the heart of my mystery' and 'though you can fret me you cannot play upon me'[9] are typical of many references of the period.

Playing stringed instruments was a recognized – and recommended – aristocratic pastime. As Henry Peacham says in *The Compleat Gentleman*, first published in 1622: 'I desire no more in you than to sing your part sure and at the first sight, withal to play the same upon your viol, or the exercise of the lute privately to yourself.'[10] Peacham's book represents an English counterpart to Castiglione's famous account of the ideal courtier, *Il Cortegiano* (1528), which takes the form of discussions held at the Ducal Palace in Urbino in 1507. The English translation of *Il Cortegiano* by Sir Thomas Hoby (1561) is interesting because of the way Hoby avoids translating some of the instruments mentioned by Castiglione literally, preferring to use the most appropriate English equivalent of his day. Thus *viola*, almost certainly used by Castiglione to mean *lira da braccio*, an instrument depicted several times in the Ducal Palace,[11] is rendered as 'lute' and 'Il cantare alla viola' as 'singing to the lute', whilst 'tutti gli instrumenti di tasti' (all keyboard instruments) becomes 'all instruments with frets'.[12] The following extract shows how Castiglione emphasizes the place of music and stringed instruments in renaissance society.

'But singing to the lute with the ditty (methink) is more pleasant than the rest, for it addeth to the words with such grace and strength that it is a great wonder. Also all instruments with frets are full of harmony, because the tunes of them are very perfect . . . And the music of a set of viols doth no less delight a man, for it is very sweet and artificial. A man's breast giveth a great ornament and grace to these instruments, in the which I will have it sufficient that our Courtier have an understanding . . . Now as touching the time and season when these sorts of music are to be practised, I believe at all times when a man is in familiar and loving company, having nothing else ado. But especially they are meet to be practised in the company of women, because those sights sweeten the minds of the hearers and make them more apt to be pierced with the pleasantness of music . . .'[13]

## The plucked instruments

Apart from the harp, all the instruments in this section are linked by their use of frets. For the basic distinctions between the various types of construction the reader is referred back to chapter 4, page 24. During the Middle Ages fretting had been inconsistent; virtually every instrument with a fingerboard, including rebecs and fiddles, had been fretted at some stage, if only occasionally; during the Renaissance the application of frets was more standardized. Whilst on all fixed-fret instruments, such as the cittern, the fretting was the job of the maker, on the movable-fret instruments, such as the lute, the responsibility was very much that of the player. Movable frets were made of gut and some idea of the mathematical complexities involved in setting them correctly can be gleaned from a study of John Dowland's instructions in the *Varietie of Lute-Lessons* (1610).[14] The number of frets inevitably varied to some extent and in any case the highest fret did not necessarily represent the upward limit of the instrument's compass. In the *Regola Rubertina* of 1542/3 Sylvestro Ganassi mentions fingering 'beyond the frets' as a part of advanced viol technique: 'It is necessary to give you a rule for playing above the frets (which is especially important for playing divisions) and up to the end of the fingerboard, as do those highly skilled players, Alfonso da Ferrara, Joan-Battista Siciliano, and also Francesca da Milano and Rubertino Mantuano. I have seen them perform the impossible on their instruments. They are certainly the most famous players today and deserve great admiration. I have seen them play above the frets as well and as agilely as if there were frets for every note.'[15] The upper reaches

of the fingerboard were clearly not regarded as out of bounds to a skilled player. During the fifteenth century and early sixteenth century the use of the plectrum was gradually abandoned, and players developed a more subtle finger-technique. The exception here was the cittern, the major plectrum instrument of the Renaissance.

The materials for string-making remained much as they had been in the Middle Ages.[16] Gut strings were spun from sheep gut, metal strings were made of soft-tempered steel or brass. Sometimes both types of metal string were used on the same instrument, steel being preferred for the higher strings, brass for the lower. The use of covered strings – those on which a central core is wound round or 'overspun', usually with brass, in order to improve the tone on low notes – did not become a regular practice until after the mid-seventeenth century. Before then the use of uncovered gut strings imposed a downward limit in pitch on plucked instruments: on the lute the sound of the lowest three strings was to some extent unsatisfactory (see below, p 77) and on the largest member of the family, the chitarrone, metal strings were frequently used. On the majority of plucked instruments, strings were arranged in pairs or 'courses', rather than singly: thus the four-course English cittern usually had eight strings. On small wire-strung instruments, such as the cittern, it was customary for the lowest strings to be made of 'twisted' strings, *ie* two strands of brass wire twisted together.[17] The question of stringing is a vexed one, however: an instrument might have some of its lower courses tuned in octaves, instead of unisons; it might have a double course in the treble or one or two triple courses in the bass, or additional unstopped bass courses which were single. Contemporary accounts do not always make such things clear; when they do, the evidence is sometimes conflicting.

All the fretted instruments developed their own idiomatic system of tuning. During the sixteenth century some maintained a single basic tuning, as the lute did: others, like the cittern and guitar, were more variable. Within the scope of this book, the aim will be to give the most commonly used tunings rather than a complete list. Associated with each tuning system was a method of notation known as tablature. Although this may look rather complicated to the layman, for the performer it is a great deal easier to read than ordinary staff notation since it actually shows him where to put his fingers. Each line of the stave represents one course of strings and a letter or number indicates which fret to use. The rhythm of the piece is shown separately above the stave. One great advantage of tablature was the way it avoided the uncertainties of *musica ficta*, the rules by which certain notes were regularly sharpened or flattened. Another advantage lay in the fact that the notation was based on interval not pitch. A piece of lute music could be played on any size of lute providing that the tuning conformed to the correct series of intervals (it is, of course, essential to know on what tuning the tablature is based). A shortcoming of tablature is that it does not show the duration of notes accurately, but with plucked instruments the sound dies quickly anyway and the general rule was to sustain notes as much as possible, particularly in contrapuntal music. The earliest printed tablature is Francesco Spinacino's *Intabulatura de Lauto Libro Primo*[18] published by Petrucci in 1507, though the tradition clearly goes back long before that. Different countries adopted their own systems of tablature; in 1511 Virdung explained the rather different German tablature system, crediting Conrad Paumann with its invention.[19] For more details the reader is referred to the excellent summaries by Gerald Hayes[20] and Diana Poulton.[21]

It is evident that professional players of plucked instruments were not restricted to reading from tablature. In Volume II of his *Syntagma Musicum* Praetorius describes situations where the players must have been able to read fluently from staff notation and improvise on the given part as well. He describes the care which must be taken 'when the lute, harp, *chitarron,* and theorbo are used as continuo instruments accompanying one or more voices; for they must at all times produce a firm, full-sounding, and continuous harmony which, as it were, carries the human voices, and they must play now intimately and softly, now strongly and freshly, according to the quality and number of the voices, and also according to the layout and location of the ensemble'.[22]

Ensemble music offered plucked instruments another quite different role too. 'If, however, the lute, theorbo, harp, *chitarron,* etc., are used as obbligato-instruments, then they, as well as the other obbligato-instruments (which are interchanged and mixed with the voices to no other end than to ornament and embellish these, and, as it were, to flavour and spice them) must make themselves heard in a different manner, and . . . decorate and embellish the melody with variations and alterations of beautiful counterpoints according to the quality of the instrument.'[23]

Praetorius gives a tantalizing example of how plucked instruments could be used together in a grand ensemble. 'Thus I once performed the appealing, immoderately beautiful 7-part motet "Egressus Jesus", by the excellent composer, Giaches de Wert [1535–96], with 2 theorbos, 3 lutes, 2 citterns, 4 harpsichords and virginals, 7 viols, 2 transverse flutes, 2 boys, 1 alto, and *einer grossen Violen* (*Bass-Geig*), without organ or regal: which gave forth an excellently splendid, lordly resonance, so that, because of the sound of the great number of strings, almost everything in the church vibrated.'[24]

**The harp**

During the sixteenth century the harp lost its old supremacy among the plucked instruments. This was partly due to the tremendous progress made in construction and playing techniques of the rival lute and keyboard families and partly due to the harp's own limitations as a diatonic instrument, discussed in chapter 4.[25] Whilst it has been suggested[26] that players produced the missing chromatic notes by stopping the strings against the cross bar, this would certainly have damped the resonance of the string and produced a marked contrast in tone, alien to renaissance taste. As with the theory that harpists re-tuned quickly as they went along, it imposed another restriction, playing with one hand only; yet virtually all iconographical evidence from the fifteenth and sixteenth centuries confirms that players used two hands, the right for the upper strings, the left for the lower ones or vice versa.[27]

Two distinct varieties of harp emerged at the end of the Middle Ages – the Gothic and the Irish – and renaissance writers describe them both. Glareanus illustrates the Gothic type in his *Dodecachordon* (1547): he shows an instrument with 24 strings tuned diatonically from F to a''.[28] Praetorius confirms this range, indicating that some harps go no higher than c''.[29] Glareanus' harp is fitted with the traditional 'bray pins', whose buzzing effect evidently went out of fashion during the next hundred years, for Mersenne tells us: 'But it must be observed that the strings do not touch the pegs at the exit of their holes, as they do when one uses *harpions*, or crooked pegs, which make them nasal. Their use has been abandoned to avoid this imperfection.'[30]

Whilst this type of harp was most often strung with gut,[31] the Irish harp was metal strung. According to Praetorius: 'The Irish harp, *harpa Irlandica* . . . has rather thick brass strings, forty-three in number, and a particularly lovely tone.'[32] The tone of the Irish harp was also praised by Francis Bacon in his *Sylva Sylvarum* published posthumously in 1627: 'No harp hath the sound so melting and prolonged as the Irish harp.'[33] Bacon also noted when writing about 'broken Musick or Consort Musick' that the Irish harp and bass viol sounded well together.[34]

Although Praetorius gives a most improbable tuning for the instrument it does seem likely, as Joan Rimmer has suggested, that by this stage some Irish harps were tuned partially chromatically. A diatonic harp with forty-three strings would otherwise have a range of six octaves, unusual at the time even on keyboard instruments.[35] The typical range of the Irish harp was similar to that of the Gothic instrument, as Vincenzo Galilei tells us in his *Dialogo della musica antica e della moderna* (1581):

'Among the stringed instruments now played in Italy there is first of all the Harp, which is none other than the ancient Cithara with many strings . . . It contains from the lowest note to the highest note more than three octaves.

'This most ancient instrument was brought to us (as Dante commented) from Ireland, where it is excellently made and in great quantities. The people of that island play it a great deal and have done so for many centuries, also it is the special emblem of the realm, where it is depicted and sculptured on public buildings and on coins . . . The harps in use among that people are somewhat bigger than ordinary ones. They have generally strings of brass, with a few of steel in the top register, like the Harpsichord. The players keep the fingernails of both hands rather long, shaping them carefully like the quills of the jacks which strike the strings of the Spinet . . . A few months ago (through the offices of a most courteous Irish gentleman) I carefully examined the stringing of that kind of harp. I find it to be the same as that which, with double the number of strings, was introduced into Italy a few years ago.'[36]

The instrument to which Galilei is referring in that last sentence is the big chromatic harp with two ranks of strings which was introduced into Italy, probably from Flanders, in the middle of the sixteenth century.[37] The demands of renaissance music made a fully chromatic compass desirable, yet with only a single set of strings a chromatic or semi-chromatic tuning created considerable technical problems for the player. The first answer was to construct an instrument with two parallel rows of strings, one a primary diatonic row, the other a secondary row which included the chromatic notes. Later on in his *Dialogo* Galilei gives a stringing plan for a large harp with fifty-eight strings arranged in two ranks[38] and he describes it as being a common instrument in Italy.[39] The second and in many ways more successful answer was a triple-strung harp on which there were three sets of strings. Joan Rimmer has defined it as follows: 'The two outer ranks are identically tuned to a diatonic scale, the centre rank is tuned to the intervening chromatic notes plus two in each octave identical with the outer ranks. From the beginning its compass has been not less than four octaves and a fifth.'[40]

The triple-strung harp was devised in Italy at the end of the sixteenth century. According to Mersenne: 'I have also been advised that the harp with three courses was invented thirty or forty years ago by Mr Luc Anthoine Eustache, Neapolitan gentleman and high officer of Pope Paul V, and that Mr Orazio Michi has brought this instrument to its perfection, which he plays very excellently.'[41] To both double-strung and triple-strung harp the name *arpa doppia* was given,[42] probably because of the increased size and compass rather than in the sense of being double-strung.

Freed from the centuries-old restriction of diatonicism the new double harp became a most useful continuo instrument and was included in the ensembles which played for the court entertainments and *intermedii*, though with nothing like the regularity of the other plucked or keyboard instruments. Amongst the most lavish of all the *intermedii* were those which took place in Florence in 1589, to celebrate the wedding of Ferdinand de Medici and Christina of Lorraine. The continuo instruments included double harps as well as various sizes of lutes, chitarrone, and organ.[43] Monteverdi not only included *Un Arpa doppia* in his score of *Orfeo*[44] (1607) but entrusted it with one of the brilliant series of obbligati which embroider Orfeo's famous 'Possente spirto' in Act III. This beautiful and expressive solo part, with its fully written-out ornaments, gives some idea of contemporary extemporized practice and the virtuosity of which the double harp was capable. It explores an exceptionally wide compass from G' to a''.

Amongst the fairly scanty repertoire for the various sixteenth- and seventeenth-century harps, the following may be mentioned:
1. The solo *tiento* for harp or organ by Alonso Mudarra, published in his *Tres Libros* (1546).[45]
2. The Robert ap Huw Manuscript *c.*1613, a cross-section of Welsh harp music written in tablature.[46]
3. The *Mottects or Grave Chamber Musique* (1630) by Martin Peerson, in which the title page includes the Irish harp as an alternative 'for want of organs' along with the virginals,

bass lute, and bandora.[47]
4. The consorts of William Lawes, for the exquisite combination of violin, viol, theorbo, and harp.[48]

Just as earlier Irish harps survived as a folk instrument both in Ireland and (as the clarsach) in Scotland, so from the end of the seventeenth century the history of the triple harp belongs almost exclusively to Wales.[49]

**The lute**

Whilst all the lute's regular names in European languages are derived from the Arabic *al 'ud* (*luth, Laute, lauto, láud,* etc.), some theorists (*eg* Praetorius) use the Latin word *testudo* (=tortoise), which was originally applied to the ancient Greek lyre with a tortoise-shell resonator. During the Renaissance the lute unquestionably occupied a special place of honour, second only to the human voice. It was the courtly instrument *par excellence* and its repertoire was enormous, only a tiny proportion being regularly heard today. The replacement of the old plectrum technique by the use of the fingers, coupled with the craftsmanship of the renaissance lute-makers, made possible a new delicacy and expressiveness in playing, a breadth of technique, and a range of nuances never possible before. The renaissance lute became the principal instrument for all kinds of what we might properly term chamber music. Its sounds were soft, intimate, and exquisite: it was an ideal partner for the human voice, a perfect match for other soft instruments, and the most eloquent of all solo instruments. The importance of the lute in renaissance music is reflected by the other arts. Philosophers discussed it, theorists endowed it with the power of Apollo's lyre, poets praised it, and painters never ceased their delight in depicting it in a wide variety of roles – the angel concerts of the fifteenth century,[50] the homely scenes of domestic music-making of the Flemish School, the voluptuous canvases of Titian, Tintoretto, and Rubens, and the narcissistic portraits of Caravaggio. In literature the lute became the legendary instrument of Orpheus, with which he charmed all Nature and attempted to lead Eurydice out of Hell: its noble classical associations are often invoked at moments of high tragedy. In the last act of Thomas Heywood's *A Woman killed with Kindness* the heroine says:

I know the lute. Oft have I sung to thee:
We are both out of tune, both out of time . . .
Go, break this lute upon my coach's wheel
As the last music that I e'er shall make;
Not as my husband's gift, but my farewell
To all earth's joy . . .[51]

Equally the lute had a role in comedy; its amorous associations (often displayed in paintings as well) can be detected in Thomas Dekker's *The Honest Whore* and John Marston's *The Dutch Courtesan,* both of whose heroines are professional lutenists of a certain kind. In Shakespeare's *The Taming of the Shrew* both Katharina and Bianca take lute lessons: the disastrous progress of Katharina's lesson is ruefully described by Hortensio:

I did but tell her she mistook her frets,
And bowed her hand to teach her fingering;
When, with a most impatient, devilish spirit,
'Frets, call you these?' quoth she, 'I'll fume with them.'
And with that word she struck me on the head,
And through the instrument my pate made way,
And there I stood amazed for a while,
As on a pillory, looking through the lute;
While she did call me rascal fiddler
And twangling Jack, with twenty such vile terms,
As had she studied to misuse me so.[52]

It is hardly surprising that the lute is so commonly referred to in Elizabethan and Jacobean literature since it was England which saw the finest flowering of lute music and produced the greatest lutenist composer, John Dowland (1563–1626). His strange melancholic genius was perfectly suited to the medium of lute songs and solos and as both composer and performer he was celebrated at home and abroad. According to Richard Barnfield's sonnet 'If music and sweet poetry agree':

Dowland to thee is dear; whose heavenly touch
Upon the lute, doth ravish human sense.[53]

Much of Dowland's early career was spent on the continent. He played at the courts of the Duke of Brunswick, the Landgrave of Hesse, and the Grand Duke of Tuscany. From 1598 to 1606 he was intermittently in the service of the King of Denmark, at an unheard-of rate of pay, and in 1612 he became one of James I's lutenists. Although Dowland initiated a whole series of song publications starting with the *First Book of Songs* in 1597,[54] surprisingly little of his solo lute music appeared in print during his lifetime. Thanks to the work of Diana Poulton we now have not only a full-length account of Dowland's life and music[55] but a complete edition of his solo compositions as well.[56]

The work of Dowland and his numerous English contemporaries marks the zenith of lute music composition, often referred to as The Golden Age. But as with the English madrigal, the development was late and comparatively short-lived. For the beginnings of the tradition we must look to Italy, where Petrucci issued the first printed books of lute music in Venice in 1507–8. One of them, the *Intabulatura de Lauto* (1508)[57] by Joan Ambrosio Dalza, consists mostly of dances, some of them arranged in suites. There are duets as well as solos and a number of free improvisatory pieces called either *tastar de corde* or *recercar*. Italy remained the most fruitful source of lute music for the first half of the sixteenth century and the work of Francesco da Milano[58] is outstanding. It is noteworthy that at this stage over half the printed music consisted of arrangements of vocal pieces; later on, more idiomatic forms such as the prelude and fantasy became more important. By the end of the century the lute repertory had become thoroughly international and was dominated by the three main schools: Italian, French, and English. The Italian solo style is well represented by the lute books of Giovanni Antonio Terzi,[59] published in 1593 and 1599, while the French predilection for the *air de cour* (graceful song with lute accompaniment) is first shown by Adrian le Roy's publication of 1571. As Michael Prynne has pointed out, [60] the interchange between countries is illustrated by the Hungarian-Polish lutenist Valentin Bakfark (Greff). His books were published at Lyons (1553), Paris (1564), Cracow (1565), and Antwerp (1569). The collection published by J. B. Besard in 1603 and entitled *Thesaurus harmonicus*[61] is a splendid compendium containing over 400 pieces and representing most of the leading lutenist composers. There were individual schools of lute-making too,[62] although their styles were much less distinct than those of the contemporary keyboard instrument makers. The best known makers worked in Italy, though surprisingly most of them were German. One of the first cities to acquire fame for its lutes was Bologna, with the work of Laux and Sigismond Maler and Hans Frei. Later in the century the lead shifted to Padua and Venice, where the name of Tieffenbrucker is pre-eminent. Members of this family worked in both cities and more surviving lutes are ascribed to the Paduan Wendelin Tieffenbrucker than to any other old maker. However, not all of these may be genuine;[63] precious few sixteenth-century lutes have survived in their original playing condition and a number of forgeries are known to exist. The Kunsthistorisches Museum, Vienna, houses a particularly fine collection of old lutes.

The delicacy and expressiveness of renaissance lute music is allied to the incredibly light construction of the instrument. The flat table, or belly, is usually made of pine, planed to as little as one sixteenth of an inch in thickness. Its most obvious feature is the carved circular sound-hole or 'rose', though equally important acoustically are the wooden bars (six or more in number) glued underneath the table to strengthen it and increase the resonance; much of the lute-maker's skill lies in the barring and in the finish of the table. The pear-shaped back is built up of a series of ribs, shaped and bent over a mould, and then glued together edge to edge. Usually made of sycamore (though cedar, yew, and cypress are used as well), the ribs are incredibly thin, often no more than one thirty-second of an inch in thickness. A well made lute is so sensitive that it literally trembles in response to the touch.[64] Of necessity the stringing must be light too, since the delicate body is unable to withstand the strain of a dozen or more strings at any kind of high tension. With the exigencies of modern concert giving in mind, some of today's lutes are rather more heavily built and tightly strung. Such instruments can produce a wide range of dynamics and project their sound well in a large hall. They demand a rather aggressive finger technique, however, more like that of the modern Spanish guitar than the true renaissance lute, and the high string-tension makes some of the intricacies of sixteenth- and

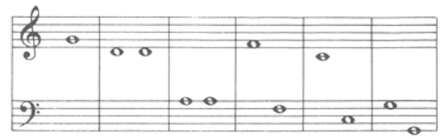
seventeenth-century ornamentation well-nigh impossible. The old writers make clear that the plucking or 'striking' action involved the soft part of the tip of the thumb or fingers, not the nails, and the movements of both hands, whether stopping or striking, should be as small as possible. To this end the little finger should rest lightly on the belly or near the treble end of the bridge, discouraging any grand sweep of the hand across the strings. A most important feature of lute playing was to allow the strings to resonate freely after they had been struck and to avoid unnecessary damping. According to the *Necessary Observations belonging to the Lute and Lute playing* by Jean-Baptiste Besard, in the translation by either Robert or John Dowland in the *Varietie of Lute-Lessons* (1610): '... nothing is more sweet, then when those parts ... are rightly combined, which cannot be if the fingers be suddenly taken from the strings: for that voice perisheth suddenly, when the stopping thereof is ended ... Therefore keep your fingers in what strings soever you strike (especially when you strike the bass) whilst the other fingers are stopping other stops, and remove them not till another note come, which doth immediately fall upon another bass, or some other part.'[65]

By the time of the first lute publications at the beginning of the sixteenth century the lute itself had become fairly standardized in stringing and tuning. Virdung,[66] followed by dozens of other writers in the next hundred years,[67] explains the typical stringing in pairs or 'courses' tuned G, c, f, a, d′, g′. This tuning became known as the 'old' tuning or *vieil accord*; it is sometimes given a tone higher. Virdung's illustration shows that the top course is single, not double, and this is confirmed as late as 1596 by William Barley in his *New Booke of Tablitur*e[68]. From Thomas Robinson's *Schoole of Musicke*[69] (1603) and Robert Dowland's *Varietie of Lute-Lessons*[14] (1610), however, we may infer that the treble course was sometimes double-strung in England in the early years of the seventeenth century. John Dowland's *Other Necessary Observations* ... which he contributed to his son's book include the instruction: 'First set on your Trebles which must be strained neither too stiff nor too slack, but of such a reasonable height, that they may deliver a pleasant sound.'[70]

This method of tuning the top course of the lute as high as it will go and then adjusting the lower strings in accordance with it, rather than trying to tune the instrument to a specific pitch, was a very practical one. The treble string (known as a 'minikin') required particularly fine gut and was very liable to break: nowadays most players use the more durable nylon for all the strings. Whilst the standard lutes were G and A lutes, with the pitch roughly equivalent to that given in the tuning given above, there were a number of smaller and larger sizes all tuned to the same series of intervals. Praetorius[71] explains that an ensemble of lutes can offer as many as seven different pitches. He lists them as follows, giving the note to which the treble string should be tuned in each case.

1. small octave lute d″ or c″
2. small descant lute b′
3. descant lute a′
4. usual choir or alto lute g′
5. tenor lute e′
6. bass lute d′
7. large octave bass lute g

Since *covered* gut strings were not developed until the later seventeenth century the bass strings were rather dull and muddy in quality, and in the sixteenth century it was customary to tune the lowest three courses in octaves rather than unisons. Thus, the most typical sixteenth-century lute tuning was as follows (the roman numerals designate the courses):



Typical lute tuning.

Dowland and other later players abandoned the octave tuning although it appears not to have entirely died out.[72]

From the many published instructions for playing the lute[73] two German authors emerge as being particularly significant. The Nuremberg lute maker and player Hans Gerle included two tutors (1532 and 1533) amongst his series of publications whilst Hans Newsidler's *Ein Newgeordnet Künstlich Lautenbuch*[74] (1536) is interesting for its series of graded pieces. Both Gerle and Newsidler seem to have provided the material for later books of instruction.
From the theoretical as well as practical point of view Vincenzo Galilei's *Il Fronimo*,[75] first published in 1568 and revised and re-issued in 1584, is particularly valuable. Galilei was a member of the Camerata, the courtly circle of poets and musicians who met regularly at the house of Count Bardi in Florence in the 1580s and 90s. *Il Fronimo*, besides emphasizing the classical background of renaissance musical thought, makes satirical reference to the contemporary additions to the lute which Galilei says will soon require as large a hand as Artaxerxes'.[76]

*Eumatio*: Dite per fede vostra quello rispose.
*Fronimo*: Mi disse esser si ritrouate, per hauere nel Liuto come nell organo, il pedale.
*Eumatio*: Ha, ha, ha![77]

(*Eumatio:* Tell me, by your faith, what he replied.
*Fronimo:* He said he had discovered a way to have a pedal on the lute, as on the organ.
*Eumatio:* Ha, ha, ha!)

Whilst Virdung makes clear that the six-course lute was standard, he also mentions the existence of five and seven courses. As the century progressed a seventh course became more common: it was usually tuned to D, a fourth below the bass course (sometimes a tone or a fifth below). From the end of the sixteenth century onwards three extra courses of bass

strings are found, tuned to C or D, E or E♭, and F. By 1630 eight courses were common. Such developments are symptomatic of the lute's struggle to keep pace with the new developments in music, particularly the demands of continuo. Alternative tunings to the *vieil accord* proliferated in equal measure. The *Trésor d'Orphée*[77] published by the French lutenist Francisque in 1600 contains several pieces marked 'à cordes avallées' (literally 'with lowered strings'). The new tunings seem to have originated in France and they include a 'Sharp Tune' of G c f a c′ e′, a 'Flat Tune' of G c f a♭′ c′ e♭′, and an *accord nouveau* or *extraordinaire* A d f a d′ f′.[78] Mattheson's complaint[79] that a lutenist spent most of his life tuning rather than actually playing reflects the inconvenient necessity of regular re-tunings, which upset the stability of the instrument. During the seventeenth century the lute's status was gradually

undermined, and it was eventually ousted in all its various roles by the baroque keyboard instruments, which could cope more easily with continuo and more brilliantly with the new solo style.

One of the best known seventeenth-century books of instruction is Thomas Mace's *Musick's Monument*[80] (1676). Mace, a great enthusiast for his instrument, resisted the lute's inevitable decline, and demands:

What is the cause, my Dear-Renowned Lute
That art of late so Silent and so Mute?

To which his lute replies:

The World is grown so Slight, full of New Fangles
And takes their chief Delight in Jingle-Jangles.[81]

Yet the lute which Mace advocates is already well removed from that of Dowland's time, being the so-called 'French lute', with two peg-boxes and a total of twelve courses tuned to the 'Flat Tune'.

**Theorbo and chitarrone**

Dissatisfaction with the sound produced by the lowest courses of the lute and the desire to improve and extend its bass register are evident as early as the mid-sixteenth century. The larger *theorbo* and still larger *chitarrone* were developed specifically as *accompanying* instruments: both have a particularly resonant lower register, made possible by the longer fingerboard and greater string length. There are two pegboxes, one for the stopped strings, the other for the extra basses which extend the range downwards diatonically. The wider spacing of the frets on the fingerboard meant that neither instrument was so well suited to the rapid fingerwork and changes of position typical of solo lute music. Praetorius writes about both instruments under the name 'theorbo'; whilst we make a specific distinction between them today, early seventeenth-century writers regarded them as interchangeable. 'Like the *viola bastarda* the theorbo is used as an accompanying instrument for sopranos and tenors, for no coloraturas and ornamentations can be executed on it because of its wide size and fretting; and thus quite a simple finger technique must be used on it. The theorbo is also very lovely to hear together with other instruments in full ensemble and whenever else it is used together with bass instruments or in their stead.'[82]

An important feature of tuning distinguishes both theorbo and chitarrone from the lute. Because of the string length it was necessary to tune the top one or two courses an octave *lower* than the corresponding lute tuning. Whilst this is no disadvantage in accompanying, it deprives both instruments of the lute's bright treble register. Nevertheless an interesting solo repertoire did develop for both instruments, exploiting their special characteristics; despite Praetorius' assertion there is an extensive use of 'coloraturas and ornamentations'. Duets were common too and include Bellerophon Castaldi's *Capricci* (1622) for two theorbos of different sizes. Kapsberger, a German nobleman, produced an impressive series of solo publications for the chitarrone which span a period of nearly forty years, starting with the *Libro Primo d'Intavolatura di chitaroni* (1604). Equally significant are the works of Alessandro Piccinini.[83] He provides some interesting information[84] about playing technique on both lute and chitarrone, describing how to arpeggiate an accompaniment, how to obtain 'sweeter sounds' by plucking half-way between the rose and the bridge (*ie* moving the hand from the standard playing position), and even recommending the use of fingernails.

Of the two instruments, the theorbo appears to have developed first; what is perhaps the earliest mention of the name (as *una tiorba*) occurs in an inventory of the Accademia Filamonica, Verona, in 1544.[85] The name (French, *théorbe, tuorbe*; German, *Theorb*; Italian, *tiorba, tuorba*) may derive from the Arabic *tarab*.[86] Its origins in Europe are obscure, the invention having having been ascribed to a number of people including Antonio Naldi, who served the Medici family, and a Signor Tiorba about 1600.[86] It seems fairly likely that the initial development took place in Italy. In *Il fronimo* (1584) Vincenzo Galilei described the additional strings on the lute and theorbo as a novelty to which he was opposed.[86] If we are to judge by the account of the seventeenth-century Dr Plume, the arrival of the theorbo in England in the midst of the threat of Popish conspiracies was not without incident. 'Inigo Jones first brought the theorbo in England *c. ann.* 1605. At Dover it was thought some engine brought from Popish countries to destroy the King, and he and it sent up to Council Table.'[87] However the portrait of Lady Mary Sidney (*d.* 1586) at Penshurst Place[88] suggests that though Inigo Jones' instrument may have caused a stir, it was not the first of its kind to reach England.

On the theorbo there were normally between fourteen and sixteen courses tuned to the *viel accord*, plus the extra bass strings. Thus Mersenne gives the tuning F′, G′, A′, B′, C, D, E, F/, G, c, f, a, d, g, or the same intervals a tone higher.[88] The strings were normally of gut and both peg-boxes were usually set in the same plane as the fingerboard, instead of being angled back, as on the lute: a mixture of single and double courses was common.[89] Mersenne's illustration shows double stringing throughout except for the treble course. As a continuo instrument the theorbo proved useful throughout the baroque period. It is regularly mentioned as a alternative to the organ and harpsichord in English song books of the later seventeenth century and Handel scored for it in *Esther* (1732) and *Athalia* (1733).

Besides the standard theorbo there was a smaller version, the *tiorbino*, of which two

examples have survived.[90] More important was the application of the second peg-box to the lute itself to help cope with the additional bass strings, a development which took place during the seventeenth century. Nomenclature becomes rather confused at this point, but the contemporary names theorbo-lute, *luth theorbé*, and *theorbierte Laute* describe an instrument which retains the basic tuning of the lute but employs the twin peg-box of the theorbo to carry the increased number of bass strings. It was customary to modify old lutes in this way, although surviving examples are comparatively rare.[91]

The largest member of the lute family is usually referred to today as the *chitarrone*; confusingly the name is an augmentation of *chitarra*, Italian for guitar. The word *archlute* (French, *archiluth*; German, *Erzlaute*; Italian, *arciliuto*), commonly applied to it today, appears however to have been normally used for the extended lute.[92] Praetorius refers to it as a *Roman theorbo* as well as a chitarrone.[97] Once again the origins of the instrument would appear to lie in Italy, and its use for vocal accompaniment was highly favoured by Italian composers.[93] In his *Le Nuove Musiche* (1602) Caccini stated that 'the chitarrone is better fitted to accompany the voice than any other instrument' and Monteverdi calls for 'Duoi chitaroni' in *L'Orfeo* (1607).[94]

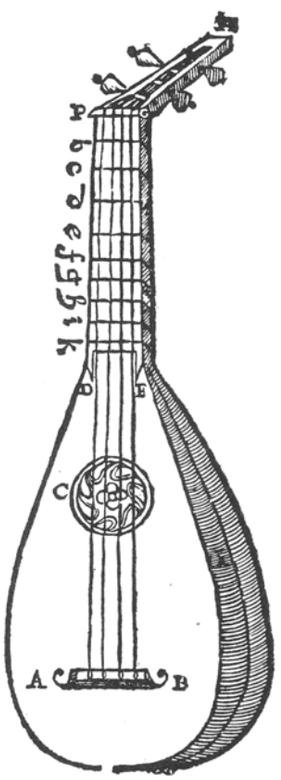
The earliest surviving examples of the chitarrone date from the second half of the sixteenth century, amongst them the magnificent instruments made by Magno Tieffenbrucker in Venice.[95] To avoid inordinate length the bass peg-box is usually doubled back on itself in the form known as a 'swan-head', and as with some of the larger sizes of lute there was often a triple rose instead of a single one. The stringing was variable, though the most common system was six double courses plus eight single basses. Metal was preferred for the basses, though gut as well as metal was used for the fingered courses.[96] For his 'Roman theorbo' Praetorius[97] gives the *vieil accord* with the top two courses down the octave (G, c, f, a, d, g) plus eight basses (F′, G′, A′, B′, C, D, E, F), and this arrangement would seem to be fairly typical.

**Mandora, pandurina, colascione, and angélique**

Four other members of the lute family should be included here. With the exception of the pandurina they are described in some detail in James Talbot's manuscript[98] and photographs of extant examples are included in Anthony Baines' *European and American Musical Instruments*.[99] Of the four, the mandora is by far the most significant, with a history stretching back at least to the twelfth century. As the reader will remember from chapter 4 (page 25) the mandora is basically a small lute; hence the Latin name sometimes given to it, *testudo minor*. In English the French spelling *mandore* is sometimes used in preference to the Italian *mandora*.[100] According to Trichet the mandora originally had no frets but later acquired nine: formerly four single strings had been common but in his day players had added a fifth or sixth string to produce what was in effect a miniature lute, or *mandore luthée*.[101] Talbot describes an *arch mandore*, a miniature archlute with seven extra basses.[102] Mersenne illustrates an instrument with four single strings, whilst Praetorius gives two tunings for a five-course instrument: c, g, c′, g′, c″ and c, f, c′, f′, c″, though many variants existed. He also mentions a smaller size, the *pandurina*, with four strings tuned to g, d′, g′, d″. He says: 'Some pandurinas have five pairs of strings and can easily be carried inside a coat. In France these instruments are said to be very common, and some musicians are so skilled on them that they can play courantes, voltes, and other French dances and songs of the like . . .'[103] He goes on to say that the pandurina could be played either with the fingers or with a plectrum.

The mandora was normally played with a plectrum and was basically an instrument of popular music-making, ideal for the treble parts of dance music. It was much used in seventeenth-century Italy and is the ancestor of the later mandolin. Trichet mentions a tutor published by Adrian Le Roy in 1585, though this has unfortunately been lost, together with a volume of mandora tablature by Pierre Brunet (1578).[104] An example of the 'classic' mandora style of the period is provided by the *Tablature de Mandore* (1626), a collection of court dances published by François, Sieur de Chancy, for his employer Cardinal Richelieu.

The *colascione* (French, *colachon*) was a European offshoot of the Eastern long-necked lute.[105] There were two or three single or double courses normally of metal, although gut seems also to have been employed.[106] The disproportionately long neck allowed for as many as 24 movable frets[105] and Mersenne[107] tells us that the belly was sometimes made half of wood and half of parchment, a method of construction still common in the East today. An early example of the colascione, made in Naples, dates from 1535.[108]



Mandora, from Mersenne's *Harmonie Universelle*.

The *angélique*, *angelica*, or angel-lute was an archlute with a long neck, sixteen or seventeen single gut strings and two peg-boxes. Its principal feature was that it was tuned diatonically: this supposedly made it easier to play and recommended it to amateurs.[109] Praetorius

quite rightly regarded it as no more than a minor novelty though a splendidly decorated *angélique* by Tielke has survived.[110]

**The cittern**

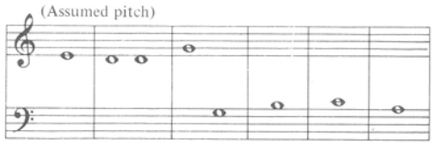
Although the lute was far and away the most widely used plucked instrument of the Renaissance, the cittern came next to it in popularity. There was an extensive solo repertoire for the instrument, both published and in manuscript,[111] the cittern was frequently depicted by artists,[112] and in Italy at least it was held in as high esteem as the lute.[113] Cittern music, like lute music, explores a wide range from simple dance tunes and ballad settings to elaborate polyphony; the technique required is every bit as demanding as that of the lute. Moreover, whilst the sixteenth-century lute was largely standardized the cittern was not: the courses varied from four to six in number and there were several 'standard' tunings. The usefulness of the cittern and the respect with which it was regarded can be seen from the number of cittern offspring which proliferated in the second half of the sixteenth century. The ceterone, orpharion, bandora, penorcon, and other more obscure relatives all share essential features of the cittern – robust construction, flat back, metal strings, and fixed frets – and they added considerably to the variety of plucked sounds available. The gut-strung lute and guitar were rather less prodigal in this respect.

It is curious that the cittern's true place in renaissance music has so often been misrepresented. Praetorius describes the four-course cittern as 'a rather ignoble kind of instrument played by cobblers and barbers'[114] and other writers ever since have been content to repeat a similarly one-sided view. It is quite true that in England especially citterns were found in barber's shops to amuse the waiting customers and the instrument's easy availability became a standing joke. Hence Thomas Dekker's jibe in *The Honest Whore:*

'Is she a whore?'
'A barber's cittern for every serving-man to play upon.'[115]

In *The Silent Woman*, Ben Jonson is equally derisive: 'That cursed barber . . . I have married his cittern that's common to all men.'[116] But, as we have already observed, the lute did not entirely escape this sort of association either, and in any case regarding the cittern merely as a barber's shop instrument is rather like thinking of the piano as an instrument only found in public houses. Thanks to recent research the cittern is once more beginning to recover its rightful place amongst the principal plucked instruments of the Renaissance. I am most indebted to James Tyler for allowing me to use material from his forthcoming book on the cittern and its music in this chapter.

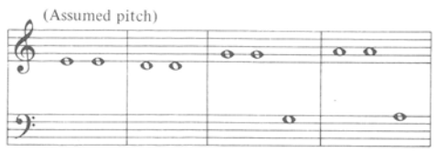
As we have seen[117] the cittern first appeared in Italy in medieval times, and throughout its long career it retained a special association with the country of its origin. From the earliest literary references in the Middle Ages it was known as *cetra*, derived from the Greek *kithara:* hence also *cistra* (French), *Cister* (German), *cithren* and other English variants. Emmanuel Winternitz[118] has shown the extent to which the cittern became a classical symbol in both the visual arts and literature: it was regarded as a revival of the kithara itself, the lyre of classical times. Whilst the early history of the cittern is obscure, information from the sixteenth century is plentiful. In his *Scintille di Musica* of 1533 Lanfranco gives the fundamental tuning for all Italian and English music.



Lanfranco's cittern tuning.

The mixture of single and double courses and the octave tuning for III are unusual, and were later discarded in favour of straightforward unison pairs. Four or five-course citterns used the same tuning, minus the lowest one or two courses. It is interesting that taken in the order III, VI, IV, V, II, I the courses describe a hexachord, the standard scale unit for all western music. Praetorius calls it the 'Old Italian' tuning,[119] though music continued to be written for it as late as 1602. The most curious feature of the cittern of Lanfranco's time (fully allowed for in the tablature) was that the fretting was *diatonic*, not chromatic as on the lute or any other fretted instrument. Tablature for this type of cittern is found as late as the eighteenth century.

Perhaps the most archaic feature of the renaissance cittern was that it retained the old plectrum technique of the Middle Ages. No source before Playford's *Musick's Delight on the Cithren* of 1666 prescribes that the strings should be plucked with the fingers as on the lute. Most instruction books, starting with the earliest surviving cittern tutor, the *Brève et facile Instruction* (*c.* 1565) of Adrian le Roy, make it clear that the strings should be plucked with a quill plectrum. By the time of Adrian le Roy's publication the cittern had become standardized as a four-course instrument in France and Northern Europe. This is what Praetorius calls the 'French' cittern[120] and the tuning was as follows with triple stringing in the lowest two courses. The fretting however, was still partly diatonic.



Adrian le Roy's cittern tuning.

In 1574 Paolo Virchi published his *Il Primo Libro . . . Di Citthara* which initiated what amounted to a cittern revival in Italy. The book's dedication reads: 'The citthara has always stood in some consideration among people because, being played with a quill, it has a lively and pleasant tone and because it has well-ordered proportion and differs little from such instruments as the lute and the harpsichord, which have already attained perfection. But it is only now that the citthara begins to delight such noble personages as the Duke of Bavaria and the Archduke Ferdinand of the Tyrol.'

Virchi's aim was to elevate the cittern to a new level of artistic appreciation. His music is predominantly of a serious nature, demanding a technique of the highest order. The instrument for which he wrote was a six-course instrument

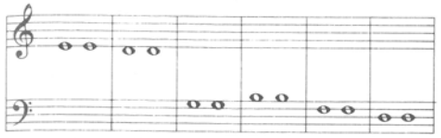
with fully chromatic fretting on which the lowest two courses were true bass strings. The tuning is as follows:



Virchi's cittern tuning.

An added seventh course (tuned to G) is also mentioned. By a great stroke of fortune a magnificent six-course cittern made by Virchi's father Girolamo has been preserved in perfect condition and is now in the Kunsthistorisches Museum, Vienna. It was made for Archduke Ferdinand in 1574, the very year in which *Il Primo Libro* was published. Since Girolamo Virchi was one of the leading makers of the Brescian school, along with Gasparo da Salò and Giovanni Paolo Maggini, it is hardly surprising that his craftsmanship is exquisite, providing the perfect vehicle for his son's music. Unlike the older style citterns, which were carved out of the solid, this instrument was a totally redesigned and 'modernized' multi-sectional construction.[121] The scrolls at the shoulders, though less pronounced than in earlier instruments, are still a reminder of the Greek kithara, with its arms and yoke. This refined version of the cittern evidently caught on rapidly; according to Vincenzo Galilei, writing in 1581: 'Today, those citterns made in Brescia are supposed to be of the highest repute. They are much used and appreciated among the nobility and, so it is said by their makers, perhaps a revival of the antique *kithara*.'[122]

Whilst Paolo Virchi's book is arguably the greatest collection of cittern music, it is closely rivalled by a number of English publications[123] in spite of the barber's-shop tradition. Although he wrote for the more restricted four-course cittern (in the tuning inherited from Lanfranco) Anthony Holborne (*The Cittharn Schoole*, 1597[124]) provides an eloquent testimonial to the skill of English cittern players. As in Virchi's music there are some wide leaps and awkward stretches for the left hand, which has to ascend to the dizzy heights of the eighteenth fret. Some of Holborne's pieces have a separate bass part (probably intended for a bass viol) which complements the cittern part and avoids the chord inversions which occur with the four-course cittern's re-entrant tuning.

Besides its solo repertoire and its role in the broken consort, the cittern was also used as a melodic instrument, as an alternative to the treble violin or viol. In his *Del sonare sopra il basso* (1607) Agostino Agazzari said that the cittern was harmonically incomplete, but best suited for *melodic* ornamentation.[125] With its plectrum to help etch out a solo line, the cittern was one of the last plucked instruments to preserve its old medieval function as a monophonic instrument.

**The ceterone**

Because of the inconsistency of spelling in renaissance times it was customary until recently to identify the *ceterone* with the *chitarrone*. However, the ceterone is in fact a true bass cittern, with a flat back and robust construction: an excellent example by Gironimo Campi is preserved in the Museo Bardini, Florence. Like the chitarrone, the ceterone has a number of additional unstopped bass strings and is particularly suitable for continuo. It may date from as early as 1524 when the Duke of Mantua ordered several *citaroni*,[126] but there is no firm evidence before the end of the sixteenth century. Agazzari (1607)[127] mentions the ceterone as a useful instrument for a continuo ensemble, and in the 1615 edition of *Orfeo* Monteverdi lists 'duoi ceteroni' as well as 'duoi chitaroni'. Praetorius mentions 'die grosse cither/Italis ceterone' in *Syntagma Musicum* Volume III.[128] In Volume II he describes a twelve-course cittern which 'produced a strong and magnificent sound like a harpsichord'.[129] He gives the tuning as: e♭, B♭, f, c, g, d, a, e, / b, g, d′, e′. There were a number of alternative methods, mostly using the traditional re-entrant tuning. The extent to which courses were single or double is uncertain.

**Bandora and orpharion**

'In the fourth year of Queen Elizabeth, John Rose, dwelling in Bridewell, devised and made an instrument with wire strings, commonly called the Bandora, and left a son, far excelling himself in making Bandores, Voyall de Gamboes, and other instruments.'[130]

Bandora by Donald Gill, Fleet, Hants. For convenience of tuning the instrument has been fitted with machine-heads (like those of the modern guitar) instead of pegs.

Thus the birth of the bandora is chronicled in Stow's *Annals*, the date firmly fixed as 1561. Four years later *bandores* were among the instruments used in the interludes to a production of Gascoignes's play *Jocasta*,[131] whilst in 1572 it was proposed that there should be a teacher of music 'to play the lute, the bandora and the cittern' in the projected Queen Elizabeth's Academy.[132] Praetorius confirms that the bandora was an English invention and adds: 'It has six and sometimes seven courses like a lute, but it is tuned differently and lacks the top strings of the lute.'

The bandora was in fact a bass instrument with a sonorous quality which perfectly complements the bright tone of the cittern in the broken consort. It was regularly used for accompanying the voice, as in Anthony Munday's *A Banquet of Daintie Conceits* (1588) published to be sung 'either to the lute, bandora, virginalles or anie other instrument' or Martin Peerson's *Mottects, or Grave Chamber Musique* (1630) 'which for want of organs, may be performed on virginals, base-lute, bandora or Irish harpe'. There is a quantity of solo bandora music too,[133] always distinguishable by its individual system of tuning. Whilst the vexed question of octave doubling remains unsettled,[134] the normal tuning was C, D, G, c, e, a, for a six-course instrument. In practice, it works well to tune the lowest pairs of strings in octaves as shown below.

By the end of the sixteenth century a seventh course was added in the bass, tuned to G′. The bandora had fifteen frets and a characteristic gently scalloped silhouette. The origin of the

name is uncertain: Donald Gill has suggested[135] that it may derive from the Spanish *bandurria*, a flat-backed instrument mentioned as early as the fourteenth century (as *mandurria*[136]). In the time of Juan Bermudo[137] (1555) the bandurria

sometimes had five strings and fifteen frets, and may possibly have been the starting point for the English instrument.

Although no English bandora has survived, an orpharion by John Rose is extant,[138] long treasured at Helmingham as a gift of Queen Elizabeth I. This remarkable instrument reveals John Rose as a persuasive advocate of wire-strung instruments: he thoroughly understood the advantages of wire stringing over the more temperamental gut, and the way in which the sturdier flat-backed construction could withstand the tension of wire strings. His instruments went far beyond the stage of mere experimentation. The bandora and orpharion are mentioned as alternative or obligatory instruments in nineteen music books published between 1588 and 1630;[139] in thirty-two household inventories made between 1565 and 1648 the bandora and orpharion occur as frequently as the lute.[140] The instruments were regularly linked together; Drayton mentions them in a poem of 1590[141] and in his *New Booke of Tabliture* (1596) William Barley describes the special touch required by the orpharion and bandora, differing from that of the lute. The fingers must be 'easily drawn over the strings, and not suddenly gripped, or sharply stroken as the lute is: for if ye should do so, then the wire strings would clash or jarre together the one against the other . . . Therefore it is meet that you observe the difference of the stroke.'[142]

The orpharion and bandora have a basically similar shape and structure, both having fifteen frets and an ingenious method of string attachment. The bridge is fixed, not movable as on the cittern, and the strings run over a small metal saddle set into the bridge and are fastened to little metal pegs driven into the lower side of the bridge. The main difference between the two instruments lies in their size and tuning. The smaller orpharion was the wire-strung equivalent of the lute and was tuned in exactly the same way. Initially it had six courses and a tuning of G, c, f, a, d′, g′, but by 1600 a seventh course had been added and thereafter the orpharion's tuning became as variable as that of the lute. Since the lute and orpharion share the same tuning they also share the same tablature. Consequently, whilst there is no specific solo repertory for the orpharion, as there is for the bandora, virtually the whole of the lute repertoire is available and appropriate to it. No less than twelve books of lute tablature published between 1579 and 1622 specify the orpharion as an alternative and as Donald Gill says: 'On the evidence of these printed music books it is clear that we are no longer justified in thinking of the vast bulk of surviving MS tablatures solely in terms of the gut-strung lute. We must think of it as much in terms of the wire-strung orpharion with its very different tonal qualities and general characteristics.'[143]

The lute and orpharion make particularly effective partners in the extensive lute duet repertoire. The contrast in timbre gives an additional spice to the music and helps to make the details of imitation clear to the listener. The 'stately' orpharion, as Barley calls it, is a superb solo instrument in its own right and deserves much wider recognition. An ingenious feature is the way the bridge, frets, and nut were sometimes set obliquely so as to shorten the treble strings but give extra length in the bass. This experimental feature was also applied to the bandora.

The development of the bandora and orpharion is basically an English phenomenon. However at the end of the sixteenth century in France there are a number of references to the *pandore*[144] (this seems to have been the usual French word) and the Trichet MS (*c.* 1640) contains a section devoted to 'La Pandore et l'Orpharion'. Both instruments were known to Praetorius, almost certainly at first hand, and they turn up sporadically on the continent (as in England) for a century or more after their invention.

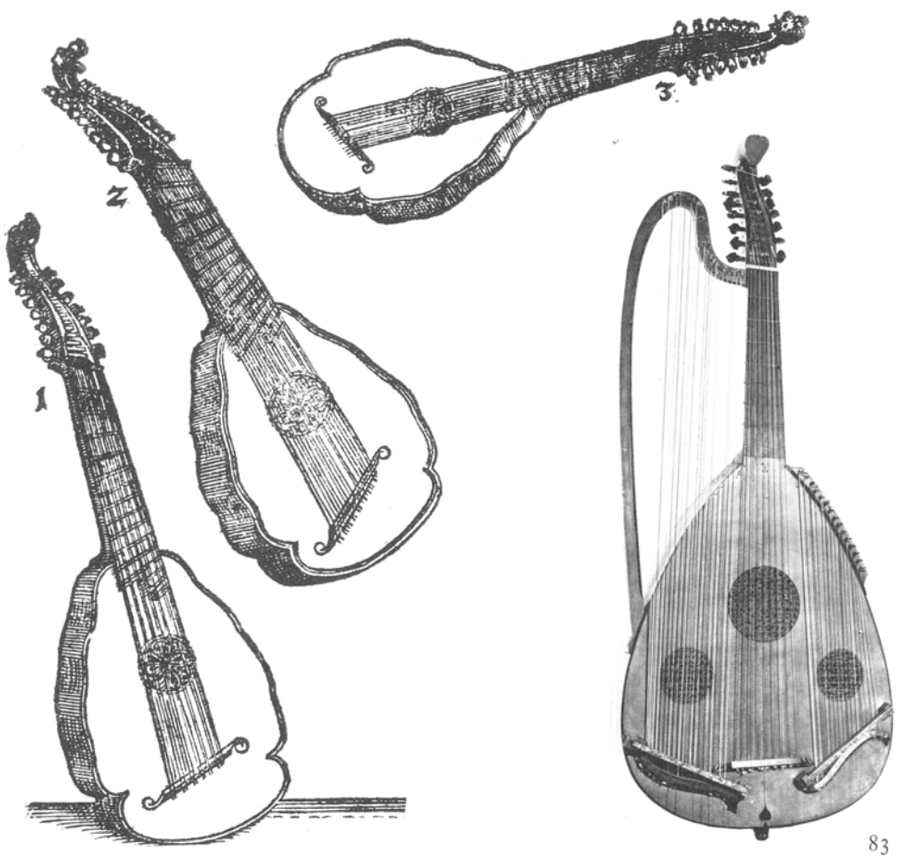
**Penorcon, poliphant, and stump**

Brief mention may be made here of three rather obscure relatives of the cittern of which no specimens have survived. The *penorcon* is mentioned only by Praetorius and is apparently somewhere in between an orpharion and a bandora. 'The Penorcon is an instrument of almost the same kind [as the bandora] only its body is a little broader than that of the bandora, and its fingerboard is quite broad, so that nine courses of strings can be strung over it. In length it is somewhat shorter than the bandora and longer than an orpharion.'[146]

According to John Playford[147] the *poliphant* (or *polyphone*) and *stump* were invented *c.*1600 by Daniel Farrant. In the *Introduction to the Skill of Music* (1683) Playford says: 'I have been informed by an ancient Musician and her Servant that Queen Elizabeth did often recreate herself on an Excellent Instrument called the Poliphant, not much unlike a Lute, but strung with wire . . .'[148]

Whilst Donald Gill believes that the instrument referred to here is more likely to have been an orpharion,[149] the poliphant certainly did exist. It seems to have been an attempt to produce some kind of cross between the bandora and the harp, and accounts by James Talbot, Randle Holme, and Francis Prujeane agree on a total of about forty strings.[150] Its range would appear to have been almost entirely diatonic.[151] The so-called 'bandora' by Wendelin Tieffenbrucker now in the Kunsthistorisches Museum, Vienna, corresponds to the various surviving descriptions of the poliphant. It has three sets of strings. On the bass side a curving harp-like frame supports twenty basses, while on the treble side across the left side of the belly are fifteen diatonic strings.[152]

Of the stump there are no surviving examples or descriptions though the name does suggest a small instrument. One piece of stump music is extant, however, entitled *Alman R. Johnson to the stump by F. P.*[153] It demands seven fingered courses, tuned to the old lute tuning, plus eight open basses, giving the impression that the stump was a wire-strung equivalent of the theorbo.[154] James Talbot does mention a



Bandora (1), Orpharion (2), and Penorcon (3) from Praetorius' *Syntagma Musicum*.

variety of orpharion which 'like the English Theorbo' carries '5 . . . rankes of open Basses'.[155] As Donald Gill says, there is nothing to suggest that the stump was a curiosity like the poliphant.[155]

**Vihuela and guitar**

The sixteenth-century ancestors of the guitar differ significantly from the modern 'classical' or Spanish guitar and certain features link them closely with the other fretted instruments of the Renaissance. Instead of fixed metal frets and single strings the early guitar and vihuela had tied-on gut frets and lightly strung double courses of gut strings which produced a tone nearer to that of the lute than the modern guitar. Players read from tablature just as lutenists did and had a wide and varied repertoire to draw on. Whilst the vihuela was a sophisticated instrument of courtly society, the guitar belongs to the more popular realms of music-making and between them the two instruments covered the gamut of sixteenth-century instrumental forms. One or two contemporary writers emphasize the fact that the vihuela and guitar share the same basic design, the chief difference being the stringing. In 1544 Miguel de Fuenllana wrote of the 'vihuela a cuatro ordenes que dizen guitarra' (the four-course vihuela called guitar)[156] whilst in the following year Juan Bermudo stated that it was only necessary to remove the top and bottom courses of a vihuela in order to transform it into a guitar.[156] He does also say, however, that the guitar was shorter (*mas corto*)[157] and the difference of size does seem to have been pronounced, the vihuela being generally much larger than the guitar. In any case the careers of the two instruments were so distinct that they are best dealt with separately.

The Spanish word *vihuela*, like the Italian *viola*, was a generic term for all stringed instruments, whether plucked or bowed, and the different types were distinguished by various qualifications, thus:

*vihuela de arco* for the bowed types
*vihuela de peñola* (or *de péndola*) for the plectrum-plucked types
*vihuela de mano* for the finger-plucked types.[158]

It was this last name (often shortened simply to *vihuela*) which came to refer specifically to the type of six-course guitar discussed here. The career of the vihuela was unique among renaissance instruments. Whilst its use was restricted entirely to Spain and to a certain extent Southern Italy, and to a relatively short period of time, in its heyday it enjoyed a prestige and a popularity accorded elsewhere only to the lute. During the years 1536 to 1576 seven major publications of vihuela music appeared in Spain,[159] representing nearly all the

principal Spanish composers. They show that the vihuela excelled both as a virtuoso soloist and an elegant accompanist, with a repertoire embracing elaborate fantasias and intabulations of ensemble music as well as numerous *villancicos*, *romances*, and *canciones*, many of which rank amongst the finest songs of the age. The vihuela was even accorded the lute's classical attributes; Juan Bermudo tells it was invented by Mercury,[160] Luis de Milán shows it in the hands of Orpheus,[161] and the fact that the lute is referred to as the *vihuela de Flandes*[162] (Flemish vihuela) suggests that to some extent the Spaniards regarded the lute as a foreign instrument.

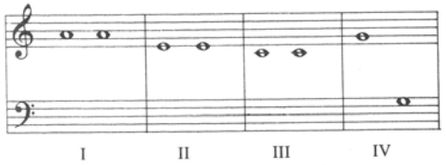
It is fitting that the first, and in many ways the best, of the vihuela publications should have come from the hands of a nobleman. Luis de Milán[168] (*c.*1500–*c.*1562) grew up in Valencia at the court of Germaine de Foix, niece of Louis XII and the second wife of Ferdinand of Aragon. His interest in current aristocratic pastimes is reflected in his first published work, the *Libro de motes de damas y cavalleros* (1535); this consists of instructions for a courtly party game of an amorous nature involving mottos and forfeits. Milán also produced a Spanish version of Castiglione's famous book, issued in 1561 as *El Cortesano*. His one musical publication, the *Libro de música de vihuela de mano intitulado El Maestro*[164] (1536) contains the first solo songs ever printed in Spain and was one of the most helpful and instructive of all renaissance instrumental tutors. The title *El Maestro* means literally 'The Teacher', and the book is carefully arranged for a beginner on the vihuela, who has to master twenty-two fantasies and six pavans before attempting to accompany his first song. Amongst various suggestions for performance, Milán includes the first indications of tempo in the history of music.

The standard tuning for the vihuela corresponds to that of the lute: the *vieil accord* of G, c, f, a, d′, g′. Milán and other writers make it clear that the vihuela varied in size, and that consequently there was no fixed pitch for the instrument. In *El Maestro*[165] Milán describes how to select strings appropriate to the size of the instrument and then start by tuning the treble course to the pitch which suited it best. Whilst the treble course could be either single or double, the lower courses were all double ones, unisons or octaves, like the lower courses on the lute.[166] Milán's instructions are for a vihuela with ten frets. It is curious that only one vihuela has been preserved from the Renaissance[167] and that vihuelas are illustrated comparatively rarely. As a result it is difficult to be sure what the most common size was, though clearly it was larger than the typical four-course guitar. Both Milán and Bermudo[168] show instruments of about the same size as a modern guitar whilst the one surviving vihuela is larger still. This very beautiful instrument has a flat back, shallow sides about half the depth of a modern guitar, a gently incurving waist, and a belly decorated with five roses.[169]

By the end of the sixteenth century the vihuela was already on the wane, and during the following century its history gradually merges with that of the guitar. By the year 1600 the guitar had achieved an extraordinary degree of popularity throughout Europe. As James Tyler has pointed out,[170] the extent to which the renaissance guitar and its music are neglected today is altogether surprising considering the immense vogue which exists for the later 'classical' instrument. Whilst most of the contents of the seven vihuela books are available today in one form or another,[159] the twenty publications for four-course guitar[171] which appeared during the sixteenth century have been virtually ignored. A certain amount of confusion has arisen through the various names which were applied to the guitar, mostly stemming from the Greek *kithara*. The Italian *chitarra*, the Spanish *guitarra*, and the French *guiterre* are the most commonly found names:[172] from the latter comes the anglicized *gittern*. The sixteenth-century gittern, however, mentioned as *gitteron* as early as 1547 in Henry VIII's Inventory,[173] is quite a different instrument from the medieval gittern and the name refers, like the other names mentioned above, to the small four-course guitar. Playford still uses the name in his *A Booke of New Lessons*

*for the Cithern and Gittern* (1652). Praetorius, who is altogether less reliable about plucked instruments than about other types, is very confusing on the subject of guitars. He uses the word *quintern* for the four-course guitar,[174] a very ambiguous name also used for the gittern, cittern, and lute.[175]

As with the vihuela, our knowledge of the early guitar is limited by a shortage of specimens. Two instruments have survived from the sixteenth century,[176] both with vaulted backs made out of a series of ribs, the method of construction used on the lute. It seems likely, however, that both flat and vaulted construction were used in the sixteenth century for both guitar and vihuela.[177] The Diaz guitar in the collection of the Royal College of Music is an amazingly light, delicate instrument about half the size of a modern 'classical' guitar. As with the surviving vihuela, the sides are quite shallow. One of the most informative sources about both vihuela and guitar is the *Declaraciòn de Instrumentos Musicales* (1555) of Juan Bermudo in which he gives the following common tuning:



Bermudo's guitar tuning.

The succession of intervals – fourth, third, fourth – corresponds to the inner courses of the vihuela. The necessity for octave tuning in the bass on a nòte as high as g gives some idea of the short string length (on the Diaz guitar roughly two feet). Bermudo also gives an alternative tuning with the bass tuned a tone lower.

The four-course guitar was especially popular in France, where it appears to have been favoured by King Henri II himself[178] and from 1550 there are a succession of French publications for the instrument, notably by Guillaume Morlaye and Adrian le Roy. The repertoire was generally light – arrangements of chansons, dances, and so on – though there are a number of more extended fantasies too.[179]

Throughout the sixteenth century the guitar is constantly linked with the cittern. As early as *c.*1487 Tinctoris[180] mentioned the *guitarra* and the *cetula* side by side as instruments of the common people. The first published book for the cittern is an appendix to Guillaume Morlaye's *Quatriesme Livre . . . De Guiterre* (1552) and Thomas Wythorne wrote that in about the year 1549 he 'learned to play upon the gittern and cittern, which two instruments were then strange in England and therefore the more desired and esteemed'.[181] Wythorne, incidentally, took a particular fancy to the gittern; in his autobiography he relates how a young girl once left an amorous verse addressed to him placed beneath the strings of his gittern.[182]

The close association of guitar and cittern, which continues up to Playford's 1652 publication mentioned above, is emphasized by the re-entrant tuning for the guitar given to Scipione Cerreto in his *Della Prattica Musica* of 1601. It will be observed that, apart from IV being unison rather than octave, the intervals are the same as in the alternative tuning of Bermudo mentioned above.

Scipione Cerreto's guitar tuning.

At this point it should be admitted that the early history of the guitar family is rather more involved than the foregoing analysis might suggest, with a certain amount of interrelation between the vihuela and guitar types. Bermudo describes a vihuela with *seven* courses[183] and Fuenllana gives music for a *five*-course 'vihuela'.[184] The latter instrument was, in fact, the five-course guitar which began to appear from the 1550s onwards and as the *chitarra spagnola* or Spanish guitar became the most popular member of the family after 1600. The regular tuning is that given by Juan Carlos y. Amat in 1586,[185] though re-entrant systems of tuning were occasionally called for as well.

Carlos y Amat's guitar tuning.

Finally, mention should be made of a number of specialized varieties of guitar which may be conveniently listed as follows:

*bandurria:* according to Bermudo this was a small three-course instrument shaped like a rebec tuned to a fourth and fifth (or *vice versa*) and played with a plectrum. Four- and five-course instruments were also known.[186]

*chitarriglia:* a smaller, higher-pitched version of the Spanish guitar.[187]

*chitarrino:* the seventeenth-century name for the small four-course guitar.[188]

*chitarra battente:* a five-course metal-strung guitar, played with a plectrum. Unlike the other members of the guitar family it has fixed metal frets.[189]

*mandola:* this ambiguous name was sometimes applied to a number of small types of guitar.[190]

## The bowed instruments

There are two long-standing misconceptions about early bowed instruments which have still not entirely vanished. One is that the viol is a medieval as well as a renaissance instrument, and the other is that the violin family somehow or other developed from it. In fact, both viol and violin families emerged within less than a century of each other – they belong to the same rather than to different generations of early music – whilst their status, technique, construction, and repertoire are quite distinct. The confusion about the period to which the viol belongs comes from the ambiguity of medieval words such as *vielle* or *viella* which are often mis-translated as 'viol'.[191] As for the distinctions between the two instruments, their typical physical characteristics *c.*1600 may be distinguished as shown in the table below.[192]

| VIOL | VIOLIN |

In general terms the violin is of more robust construction than the viol. On the latter instrument the wood is thinner throughout and the strings are lighter, longer, and less tense.[193] The playing positions involved were equally distinct. All the viols were played in a sitting position, the player holding the instrument vertically on or between his knees, whilst the smaller members of the violin family were played under the chin or on the shoulder, resting more or less horizontally on the arm. Hence the qualifications *viola da gamba* (leg-fiddle) and *viola da braccio* (arm-fiddle). The bow grip was different also, the viol bow being held underhand with the fingers controlling the tension of the horse-hair whilst the violin bow was held overhand, albeit with a quite different grip from that used today. The bow itself presented one common feature, on whatever instrument it was used: the inward camber found on modern bows did not appear until the mid-eighteenth century.[194]

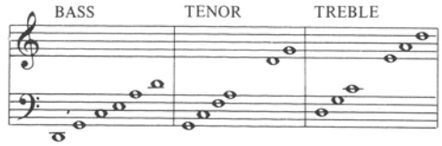
**The viol**

From the details already given the reader will have observed the many similarities (tuning, fretting, light construction and stringing, etc.) between the viol and the plucked instruments of the Renaissance. It may be added that throughout the sixteenth and seventeenth centuries it was customary to write certain types of viol music in tablature. Whilst its precise origins remain obscure, there is little doubt that the viol came into being just as the earliest bowed instruments did: by the application of the bow to a pre-existing plucked instrument. One or two renaissance paintings clearly illustrate the transition: players are shown seated, holding the instrument guitar-style across the knees, whilst the right hand desperately tries to find some comfortable way of bowing.

It was natural that the position of the instrument should change from the horizontal to the vertical, with the bottom end gripped by the knees. The most widely accepted theory[196] is that the viol developed in Spain during the second half of the fifteenth century. Several Italian renaissance writers hint at this,[196] and the most obvious plucked equivalent to the viol is certainly the vihuela whose shape, size, and tuning correspond with that of the tenor viol. Viol-making and playing first seem to have caught on in Italy, however.[197] In Germany a common early sixteenth-century name for the viol was *welsche Geige,* literally 'foreign fiddle' (the word *Geige* was used, like the Italian *viola* and the Spanish *vihuela,* as a generic term). In England a consort of viols first makes an appearance in the records of the King's Music for 1540: six of the players are Italians, from Cremona, Milan, and Venice.[198]

One thing is certain: the outward appearance of the viol varied enormously during the first hundred years or so of its existence and only became standardized after 1600. What we tend to think of as the typical viol design was only one amongst the many shapes and sizes of the sixteenth century.[199] A particularly interesting transitional shape is that shown by Virdung in his *Musica getutscht:* it has the bent-back pegbox of the lute together with the central rose and fixed bridge common to the lute and guitar. The omission of a movable bridge – an essential feature unless all the strings are to be sounded at once – seems altogether curious. Gerald Hayes regarded the omission as a mistake,[200] though if that is the case it was a mistake cheerfully repeated by Agricola in his *Musica instrumentalis deudtsch* in the editions of both 1528 and 1545. Since Virdung and Agricola show the bridges quite clearly on the rebecs which they illustrate, one cannot avoid the suspicion that the *Gross Geigen* or *dreierley Geigen* were chordal instruments on which all the strings *were* sounded simultaneously. The existence of nine strings on Virdung's instrument is difficult to credit otherwise. Instruments of this shape certainly existed: one or two surviving sixteenth-century instruments do have the same narrow waist and sharply incurving sides.[201] though not in conjunction with the sharply angled peg-box. Stringing was variable too. Five-string viols are found at every period[202] and Agricola tells us that his discant, altus, and tenor instruments have five strings, even though his illustrations show only four.[203] In his *Epitome musical* (1556) Philibert Jambe de Fer says that viols in France had five strings tuned in a series of fourths whereas Italy had viols with six strings.[204] During the baroque period a seventh string was sometimes added to the bass viol to extend the range downwards.

Virdung omits the tuning of the viols which he describes and so the first account we have is that of Agricola in 1528.[203] Although the nomenclature of different sizes does not correspond with later practice (Agricola's 'bass' being equivalent to the normal tenor) the lowest tuning he gives corresponds to the lute or vihuela: G, c, f, a, d′, g′. In Sylvestro Ganassi's *Regola Rubertina,*[205] published in Venice 1542–3, the three standard sizes of viols and their tunings are clearly set out.



Viol tunings from Ganassi's *Regola Rubertina.*

The wide range of each size of viol made the existence of an alto viol unnecessary. In the seventeenth century a few large treble viols were made, however, tuned a tone lower than the treble (starting on c) and designated 'alto'. The tenor viol was sometimes tuned a tone higher (starting on A): this was part of what Mersenne[206] called 'tuning in the Italian manner'.

Ganassi's *Regola Rubertina* shows that an advanced standard of viol playing had been developed before the middle of the sixteenth century. As in his companion tutor for the recorder, the *Fontegara,* Ganassi gives precise details of technique: much of the information about holding the instrument, fingering, bowing, and making divisions is most valuable[207] and the range he explores is impressive, covering

Grossen Geigen, from Agricola's *Musica instrumentalis deudtsch.*

as it does nearly four octaves.[208] Ganassi explains how the viols could be used, like the lute, to accompany singing: as an illustration he gives a madrigal, *Io vorei Dio d'amor,* arranged for the voice to sing one part and two (occasionally three) other parts to be played on the viol. This was a method of self-accompaniment, Ganassi tells us, which had been vigorously explored in his day, and he mentions two notable men who excelled at it, Juliano Tiburtino and Lodovico Lasagnino, both of Florence.[209] He compares this chordal use of the viol with that of the *lira da braccio* and notes that the differences between the instruments necessitates a considerable difference in treatment.[210] Nevertheless, as often happens with renaissance theorists, sound common sense is found side by side with absolute nonsense. Ganassi is at pains to establish a good classical pedigree for his instrument and at one point he refers to ancient statues as the source of information for bowed instruments in antiquity. He uses the word 'violone' for the viol.

'Notice how the violone is made with six strings. I often wondered which was more ancient, the lute or the violone, when I wanted to describe its origin. Having discussed the question with various people, I recalled having seen among the antiquities of Rome . . . one figure who had in his hands a bowed viola similar to those mentioned above. There I immediately recognized that the violone was more ancient than the lute, on the evidence of the story of Orpheus, who is not mentioned as using the lute, but rather the instrument with strings and bow that is the lira, which with its strings and its bow is like the violone. But as to its name, it was lira or lirone, although most people call it violone. But it is more correct to call it lirone, and, in the plural, lironi, rather than violone, or violoni; our evidence is based on Orpheus and his lyre . . .'[211]

Absurd as it sounds today, all this was taken seriously and, as mentioned earlier on, the viol shared the aristocratic attributes of the lute and was cultivated amongst courtly society and later by gentleman amateurs. Perhaps it was occasionally cultivated a little too seriously, for in England the viol became a regular subject of jest amongst the dramatists, having the connotation of an affected ass. Sir Andrew Aguecheek 'plays o' the viol de gamboys', Sir Toby Belch tells us,[212] and in Ben Jonson's *Every Man out of his Humour* Sir Fastidious Brisk courts Saviolina whilst scraping away on the bass viol and puffing tobacco.[213] Perhaps the most amusing reference is that in Thomas Middleton's *A Trick to Catch the old One* where Onesiphorus Hoard takes pride in his niece's accomplishments as follows: 'The voice between her lips, and the viol between her legs, she'll be fit for a consort very speedily.'[214]

By the beginning of the seventeenth century there was certainly every encouragement for amateur and professional alike to learn to play the viol, since the repertoire for the instrument was considerable, and embraced some of the finest music of the age. A consort of viols provided the perfect instrumental combination for renaissance polyphony: sonorous, flexible, and sustained, viols can make clear every detail of a complex five- or six-part texture. The *in nomines*, pavans, and fantasies by composers such as Byrd, Coperario, Ferrabosco, Gibbons, Lupo, Tomkins, and many others form an exquisite chamber music repertory which, in the case of many of the lesser known composers, has still not been fully explored.[215] The tradition continued through the seventeenth century with the work of Jenkins and Locke to the wonderful set of fantasies by Purcell[216] which form the culminating point in the development of viol consort music. Consort songs were popular too;[217] viols provide an ideal accompaniment to a solo voice, particularly in laments such as 'Pandolpho' by Robert Parsons[218] or William Byrd's 'Ye Sacred Muses', an elegy on the death of Thomas Tallis (1585).[219]

Whilst the English developed a particular predilection for viol playing and consort music, there was plenty of activity on the continent too. Praetorius makes it clear that the use of a consort of viols was an everyday matter[220] though he suggests a rather different performance practice. The standard combination of viols for seventeenth-century English music would have been that set out by Thomas Mace in; 1676: 'Your *Best Provision* (and *most Compleat*) will be, a *Good Chest of Viols; Six,* in *Number;* viz. 2 *Basses,* 2 *Tenors* and 2 *Trebles:* All Truly, and *Proportionably Suited.*'[221]

Praetorius says that when the English play their viols, the tuning is somewhat higher than that to which he is accustomed.[222] His chief tunings are: bass G′, C, F, A, d, g; tenor D, G, c, e, a, d′; treble G, c, f, a, d′, g′. Thus the bass and treble are a fifth lower, and the tenor a fourth lower, than the standard tunings quoted from Ganassi above. Similar low pitches are confirmed by other writers, including Zacconi (1592) and Banchieri (1609).[223] The discrepancy is all the more puzzling since it cannot just be one of pitch; Mace's chest of viols tuned as Praetorius suggests would make a miserable noise, since the stringing would be too low for the instruments. Praetorius can only mean that he is used to a viol consort of *larger* instruments, with (in English terminology) tenors for the top parts, basses for the middle parts and extra large basses for the lowest parts. Yet if such a deep-pitched consort existed what did it play, since consort repertoire descending to G′ is conspicuously lacking? An answer has recently been provided by Michael Morrow in a stimulating article[224] chiefly concerned with two publications by Hans Gerle: *Musica Teusch* (1532) and *Musica und Tabulatur* (1546). 'Gerle states that the normal four-part viol consort consists of a tenor in A, two basses in D and a contrabass in A (the latter, however, lacking the bottom A string).'[225] Gerle's music for viol consort,[226] the earliest to be printed, employs an apparently normal compass descending to F. Since it was printed in tablature, however, Gerle was able to make clear that each instrument was to be used in its upper register, ascending as high as the fifth – or even seventh – fret on the top string.[227] The effect of a consort of viols used in this way would certainly be totally different from the accepted 'English' sound: the evidence of Praetorius and the other writers mentioned above suggests that such a practice may have been quite widespread.

**The violone**

From the mid-sixteenth to the mid-seventeenth century the viol family was complemented by some kind of double bass instrument, usually referred to today as the *violone,* of which a few rare examples have survived.[228] As Francis Baines has pointed out,[229] the name is somewhat ambiguous as far as early usage is concerned. Ganassi uses 'violone' to refer to the normal bass viol, Ortiz uses it to refer to all the viols, whilst in the baroque period both Corelli and Handel used it for the cello.[230] In his *Musikalische Exequien* Schütz uses 'violone' for

the *gross Bassgeige*, an instrument a little larger than the cello.[231] Further confusion arises from the fact that up to the eighteenth century the name 'violone' was regularly used for the double bass, a much more common instrument than the true violone. As a result it has often been stated that the modern double bass belongs to the viol family, not the violin family, although this idea has been effectively challenged by Eric Halfpenny.[232] Nevertheless, the double bass itself was the least standardized member of the violin family; during the seventeenth and eighteenth centuries it was commonly built with five strings, provided with a fretted fingerboard, and bowed underhand,[233] all of which has naturally led to confusion with the violone.

Even when we restrict the term 'violone' to members of the viol family, an element of uncertainty remains. It was clearly a six-string instrument, more lightly constructed than the double bass, and fretted and tuned like a viol. But what was it tuned to? Banchieri[234] describes a *violone in contrabasso* tuned an octave below the bass viol, *ie* D′, G′, C, E, A, d. This is a true contrabass instrument, operating at 16-foot pitch. The violone illustrated by Praetorius is a 16-foot instrument too, and it is of huge proportions: according to the scale he gives it would stand nearly eight feet high.[235] Yet most of the surviving instruments are relatively small. Should they then be tuned an octave lower than the bass viol, or to some intermediate tuning such as mentioned by Gerle for his largest size of viol?

There is a great deal of evidence to suggest that the 'normal' violone tuning was not a full octave below the bass, and that the instrument was not a true 16-foot instrument at all. Banchieri also speaks of a *violone da gamba*, tuned G′, C, F, A, d, g,[236] as the true bass of the consort[237] and there is corroboration from Gerle, Zacconi, Cerone, and Praetorius.[228] Rather than doubling the bass part at the octave, the most common function of the violone may well have been to provide the bass part of consort music on its own, such as in the set of fantasias a 3 'with the double-bass' by Orlando Gibbons.[239] Nevertheless, most violones played today are tuned an octave below the bass viol and are commonly used for octave doubling as the baroque double bass was.

**Division viol, lyra viol, and viola bastarda**

From the mid-sixteenth century the viol started to develop its own solo repertory. In his *Regola Rubertina* Ganassi provided players with a number of studies similar in character and purpose to the early lute ricercars, and employing double- and even triple-stopping. Ten years later the Spaniard Diego Ortiz issued his *Tratado de Glosas* (Rome 1553),[240] giving viol players some splendid sets of divisions over popular basses such as the *Romanesca* or chansons such as *O felici occhi miei*.

For rapid solo work a slightly smaller version of the standard bass viol was developed, sometimes called the 'division' viol, a name immortalized in the title of Christopher Simpson's publication of 1665.[241] Simpson says: 'A Viol for Division, should be of something a lesser size than a Consort Bass; that so the Hand may better command it: more or less short, according to the reach of his fingers who is to use it . . . The sound should be quick and sprightly, like a Violin.'[242] Simpson goes on to give a full account of the construction and playing of divisions: 'These several sorts of Divisions are used upon the Bass-Viol, very promiscuously, according to the Fancy of the Player or Composer . . .'[243]

Judging from his compositions, Simpson was a highly skilled performer: by his time England had become noted for its viol playing and English violists were much sought after, often being met with on the continent.[244] From about the year 1600 an idiomatic solo style had developed, known as 'playing the lyra way'. There is an extensive repertoire[245] for the so-called 'lyra viol' which may be regarded as a parallel development to the solo lute repertory of the seventeenth century, since it was written in tablature and involved a variable system of tuning to suit the nature of each piece. 'Playing the lyra way' explored the technical possibilities of the viol to the full: it made extensive use of double- and triple-stopping and even employed special effects such as pizzicato. A selection of the tunings required by lyra-viol music is given opposite. The majority of them involve the use of fifths to widen the overall compass and facilitate the stopping of full chords.

Amongst the composers who wrote lyra-viol music the eccentric personality of Tobias Hume[246] (d. *c.*1645) is outstanding. His *The First Part of Ayres*[247] was issued in 1605 with the punning title 'Musicall Humours' printed at the top of every page. The titles are fanciful such as 'My Mistresse hath a pretty thing', 'Tickle me quickly', and 'Hit in the middle', though Hume includes a number of expression marks and directions for interpretation including 'Drum this with the back of the bow' – the first *col legno* in history. As did a number of other composers, Hume wrote music for two and even three lyra-viols together as well as solo pieces.

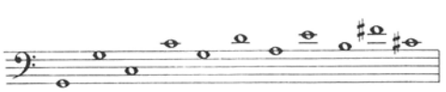
It should be emphasized that any viol could be tuned and played 'the lyra way' and it was not necessary to obtain a special instrument to play lyra-viol music. One or two purpose-built 'lyra viols' have survived, however;[248] they are slightly smaller in size than the division viol. Praetorius describes such an instrument ('its body is somewhat longer and larger than that of a tenor'[249]) calling it the *viola bastarda*. He mentions an unusual English version which in addition to the six gut strings had a set of eight or more sympathetic metal strings laid underneath.[250] In *Musick's Recreation on the Viol, Lyra-Way* (1661) the invention is attributed by John Playford to the ingenious Daniel Farrant, though it would seem to have enjoyed a fairly short-lived existence. Playford says: '. . . by the striking of those Strings above with the *Bow*, a Sound was drawn from those of Wire underneath, which made it very Harmonious. Of this sort of *Viols* I have seen many, but *Time* and *Disuse* has set them aside.'[251]

However, Praetorius' statement that the *viola bastarda* was used mainly as an accompanying instrument, like the theorbo (see p. 78), seems to be mistaken. All the repertoire for it from Girolamo dalla Casa (1584)[252] onwards makes it clear that the *viola bastarda* was a virtuoso speciality, using a normal small bass viol in *normal tuning*, and is not in any way to be confused with the idiosyncrasies of the lyra viol. In other words, the *viola bastarda* was simply the continental equivalent of the English division viol. However, modern writers have regularly repeated Praetorius' assertions to the contrary.

**The lirone**

One relative of the viol was developed as an entirely chordal instrument. This was the *lirone* or *lira da gamba*, a marriage of the bass viol with the *lira da braccio* (see below). The typical features are found on the instrument made by the Paduan lute-maker Wendelin Tieffenbrucker *c.*1590, and now in the Kunsthistorisches Museum, Vienna: intricate outline, *S*-holes, broad neck, frontal pegs, flattish bridge, and drone strings set to the side of the fingerboard. A rather different type, named *lirone perfetto* in one source,[253] is preserved in the Brussels Museum of Musical Instruments: the outline is plainer, there is a rose as well as *f*-holes, and there are no drone strings.[254] Apart from the drone strings, the lirone had from nine to fourteen stopped strings, tuned in fourths, fifths, and octaves.[255] Cerreto, Praetorius, and Mersenne give various different tunings; of the three writers it is Cerreto who gives us the most detailed account of playing techniques.[256] He illustrates how to play accompaniments with chords of from four to six notes, and emphasizes that even in a solo part players should still use a chordal technique. Cerreto assures his students 'that if in the strokes they touch upon some other string, it will not matter provided the same concord is maintained. It is difficult, especially when playing on the middle strings, to avoid touching more than one string because the bridge is only slightly arched.'[257] The tuning he gives is as follows:



Lirone tuning given by Scipione Cerreto.

Writing about the lirone Mersenne says: 'Now the sound of the lyre is very languishing and suitable for exciting devotion and causing the spirit to commune with itself; it is used to accompany the voice and recitatives . . . There is no instrument which represents so well the music of Orpheus and antiquity.'[258]

The lirone was mainly used in Italy *c.*1550–1650 in court entertainments, *intermedii*, and operas. Cerreto mentions the existence of no less than seven masters of the lirone in Naples in his day, and 'un lirone' appears several times in the *intermedii* of 1565 by Striggio and Corteccia.[259] In 1567, Cosimo Bartoli praised Alessandro Striggio (the elder) 'who is . . . even more than excellent in playing the "viola" [*ie* lirone], and he plays on it in four voices at one time with such elegance and fullness of tone that he amazes the listeners'.[260]

**Renaissance fiddle and lira da braccio**

We can now turn from the instruments held and played *da gamba* to the *da braccio* types. Before the advent of the violin family there were three main types of bowed instruments played on the arm: the rebec, already fully dealt with in chapter 4, the renaissance fiddle

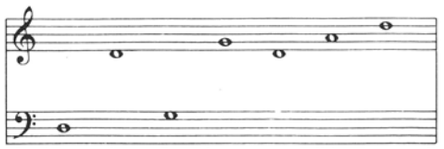
(a matured version of the medieval fiddle), and the *lira da braccio* which may be regarded as an offshoot of the fiddle. The name *viola da braccio,* which first occurs in 1543, was first used as a generic term like the older *viola,* but gradually came to refer to the members of the new violin family.[261]

By 1500 the typical renaissance fiddle had five strings, one of which might be an unstopped drone. It had developed a multi-sectional construction with a separate neck, fingerboard, top, back, and connecting ribs. Although it was quite regularly fretted, the appearance of the fiddle closely foreshadowed that of the violin: both were treble instruments of a comparable size.[262] During the second half of the fifteenth century the *lira da braccio* had evolved as a distinct type. Its outline resembled that of the violin too, although it was larger, generally more like a modern viola in size. It had seven strings, two of them drone strings which ran off the fingerboard, and at least until after 1600, frets do not seem to have been used. Praetorius gives the following tuning, reminiscent of medieval fiddle tunings:



Tuning of the *lira da braccio* given in Praetorius' *Syntagma Musicum.*

The importance of the *lira da braccio* in Italian renaissance culture has been shown by Emanuel Winternitz.[263] Like the lirone, which developed from it, it was primarily a chordal instrument as Winternitz says, 'used by recitalists who improvised polyphonic accompaniments for their singing, and therefore one of the most characteristic implements of the intended rhapsodic art of the ancients'.[264] Many writers accepted the idea that the *lira da braccio* was, in fact, an ancient instrument. Like the classical lyre it had seven strings, two of them unstopped strings which always sounded for their full length like those of the lyre. Even the kithara's plectrum was credited with being some kind of fiddle bow. In mythological scenes both Apollo and Orpheus are found holding the instrument: equally, the *lira da braccio* is often shown hanging up by way of symbolic inspiration to some worthy humanistic scholar of the Renaissance.

The *lira da braccio* must not be regarded merely as a toy of theorists and dilettantes. It occupied a central position in the musical performances of Italian courtly life, particularly in the first part of the sixteenth century. At the courts of Ferrara and Milan virtuosi of the lira da braccio were employed.[265] In his discussion of the musical interests of Leonardo, Vasari stresses his predilection for the instrument. Leonardo was a man 'who by nature possessed a spirit both lofty and full of grace which enabled him to improvise divinely in singing and playing the lira da braccio'.[266] According to Vasari, it was as a player of the lira da braccio that Leonardo was introduced to the Milanese court in 1494 and presented to the Duke.[267]

**The violin**

Having reached the instrument which of all those dealt with in this book is the most universally familiar today, it is tempting to follow Praetorius and say: '. . . since everyone knows about the violin family, it is unnecessary to indicate or write anything further about it.'[268] Yet after a gap of three and a half centuries, the early history of the violin is far from clear. For a comprehensive survey of the instrument before 1600, the reader is referred to the first part of David Boyden's fascinating study *The History of Violin Playing,* which takes Praetorius' cryptic remark as its starting point. As David Boyden says,[269] what everyone knew then nobody knows now, and it is frustrating that whilst the *Syntagma Musicum* is a mine of information about such relative obscurities as the *Geigenwerk* and tromba marina, the family which was to become the most important in Western music is curtly dismissed.

Praetorius might well have been able to give a precise answer to the question which has fascinated many historians since his time: when, where, and by whom was the violin invented?[270] Today we must be content with placing the emergence of the violin as *c.*1550 in Italy, after some twenty or thirty years of experimental designs. The earliest representations of the new instrument are found in paintings executed by Gaudenzio Ferrari (*c.*1480–1546) in the early 1530s.[271] At this early stage the three component members of the violin family are already clearly distinguished: treble, alto-tenor, and bass, equivalent to the three principal sizes of the viol family.[272] Whilst the instruments have most of the violin's features – typical outline, scroll, bulging back, *f*-holes, and overhand grip for the bow – there are only three strings. On the early three-string violin the tuning was g, d′, a′ corresponding to the lowest three strings of the fully developed instrument.[273] It is sometimes stated that since *violino* is a diminutive of *viola,* the viola must have been the first member of the family to develop. But as David Boyden has

shown[274] all the evidence suggests that the violin emerged as a family: to start with, the term *violin,* unqualified, might refer to a treble, alto-tenor, or bass instrument, and whilst it gradually came to refer exclusively to the smallest member of the family, Venetian composers still used *violino* for the viola as well as the violin at the end of the sixteenth century.[275] Giovanni Gabrieli wrote a part labelled *violino* in his *Sonata Pian' e Forte* (1597) which descends below the violin's bottom string and is clearly intended for the viola.[276]

The first positive evidence for the four-stringed violin family comes in 1556 with the *Epitome Musical* of Philibert Jambe de Fer: 'The violin [*violon*] is very different from the viol [*viole*]. First of all it has only four strings, which are tuned in fifths . . . The form of the body is smaller, flatter and in sound it is much harsher [*rude*].'[277] Jambe de Fer gives the standard modern tunings for the upper two members of the family (*violon* and *haute contre-taille*), whilst his *bas* is a tone lower than the modern cello, a tradition which persists in France up to the time of Mersenne.[278] Particularly interesting are the

Tunings for the violin family given by Philibert Jambe de Fer.

hints which Jambe de Fer drops about the violin's musical status compared to the viol.

'Why do you call one type of instrument viols and the other violins?'

'We call viols those with which gentleman merchants and other virtuous people pass their time . . . The other type is called violin; it is commonly used for dancing, and with good reason, for it is much easier to tune . . . It is also easier to carry, a very necessary thing while leading wedding processions or mummeries . . . I have not illustrated the said violin because you can think of it as resembling the viol, added to which there are few persons who use it save those who make a living from it through their labour.'[279]

Throughout the second half of the sixteenth century the violin was an exclusively *professional* instrument, just as the shawm and cornett were, and its principal repertoire was dance music. It comes as no surprise that hardly any specific repertoire for it survives for this period: the violin is mentioned as an alternative to the viol in one or two publications, such as Anthony Holborne's *Pavans, Galliards, Almans and other Short Aeirs*[280] of 1599, Morley's *First Book of Consort Lessons*[281] of the same year, and Dowland's *Lachrimae*[282] of 1605. The earliest printed music for violin consists of two dances which formed part of the *Ballet comique de la reine* performed for a royal wedding festivity at the French court in 1581.[283] Violins had been popular there since the importation of an Italian dance band of violins led by Balthasar de Beaujoyeulx in about 1555. In Britain the violin became a regular town bandsman's instrument, though apparently it was not always well played. When Mary Queen of Scots arrived in Edinburgh in 1561, the French chronicler Brantôme describes how 'In the evening as she [the Queen] wished to sleep, five or six hundred scoundrels [*marauts*] of the town serenaded her with wretched violins and small rebecs, of which there is no lack in this country; and they began to sing psalms than which nothing more badly sung or out of tune could be imagined. Alas, what music and what repose for her night!'[284]

In Italy the violin quickly became more versatile and made its way into more elevated company. We find it regularly amongst the instruments required for the courtly *intermedii,* such as those of Florence in 1589 which celebrated the wedding of Ferdinand de Medici to Christine of Lorraine. The Sinfonia by Luca Marenzio which introduced the second *intermedio* included a *violino* playing with lutes, harp, chitarrone, two liras, *basso di viola,* and *viola bastarda.*[285] Needless to say, the theorists hastened to furnish the violin with an honourable pedigree. According to Bernardi in his *Ragionamenti musicali* of 1581: 'The violin was invented by Orpheus, son of Apollo and Calliope. The ancient poetess Sappho invented the bow fitted with horse-hair, and was the first to use the violin and the viola in the way they are used today; and this happened 624 years before the coming of our Lord Jesus Christ.'[286]

The violin's true pedigree was rather mixed since it represented a fusion of the noble *lira da braccio* with the renaissance fiddle and the much less elevated rebec. Nonetheless, the violin derived great strength and richness from its triple parentage: the instrument which emerged in the middle of the sixteenth century had an outstanding potential for expressiveness, agility, and sonority. And as everyone knows it had the most incredible success story of any instrument in the whole history of music. Within fifty years it had conquered any initial doubts and prejudices, within a hundred it had invaded every sphere of musical life, church, chamber, and opera house, it had laid the foundation of the string section of the modern orchestra, it had developed an enviable and already prodigiously difficult solo repertoire, and as far as any kind of instrumental ensemble was concerned it had eclipsed all other instruments.

Of course, none of this would have been possible without the artistry and craftsmanship of the early violin-makers. And perhaps theirs was the most remarkable achievement – to bring a new instrument to the peak of perfection in such a short period. The great school of makers was centred in two Italian cities. At Brescia there was Gasparo da Salò who died in 1609, and Paolo Maggini who died about 1632. At Cremona there was the Amati family, stretching from Andrea, who died about 1580, to his grandson, Nicola, who died in 1684. And in the following century Cremona was the home of the greatest violin-maker of all time, Antonio Stradivari.

2 The projected series of five books by Gerald Hayes, *Musical Instruments and their Music 1500–1750*, was interrupted by the Second World War after only two volumes had appeared. Vol. II, 'The Viols, and other Bowed Instruments' (O.U.P. London 1930), remains the longest study in English of the bowed instruments of this period, although new facts have come to light since then. Much of the fruit of Gerald Hayes' research is to be found in his contributions to volumes III and IV of the *New Oxford History of Music*.

Where did the crumhorn come from? When did the sackbut develop? What is the difference between a cittern and a gittern? How does the hurdy-gurdy work? These and a multitude of other questions are answered in this comprehensive guide to European musical instruments before 1600. Full details are given of the origin, development, and use of each instrument; great attention has been paid to the historical and social background. There are over 200 illustrations, including contemporary paintings and woodcuts, and photographs of original instruments and modern replicas, as well as charts, tables, and diagrams.

As André Previn writes in his Foreword: 'No one is better qualified to write on this subject than David Munrow. His practical experience and theoretical knowledge have produced a book which will appeal to the specialist and general reader alike. His ability to mix scholarly detail with amusing stories should make this volume fill a place on thousands of bookshelves.'
